Dayton-Dowd Type CSU Automatically Balanced Three-Stage Centrifugal Pump

Illustration shows upper half of casing lifted. Note ease of access to all working parts. This is but one of the few points of merit of this type of Dayton-Dowd CSU Centrifugal Pump. Simple in design and rugged construction insures reliability in service and durability. Absence of diffusion vanes adds greatly to its life and reduces maintenance expense. Original and advanced in design and absolutely guaranteed to perform the service for which it is sold.

Type CS Single Stage, Double Suction Volute Centrifugal Pump

Non-overloading type, and so designed that the power consumed under any conditions of variation will not exceed the power required under normal operation. This feature protects the motor from being overloaded. This pump contains all the good features of Dayton-Dowd construction.

In Use in Prominent Plants

Parliament Buildings, Ottawa, two 2″ type CSU, 2 stage centrifugal pumps.
Toronto Union Station, Toronto, eleven type CS, single stage pumps.
Bridgeburg Water Works, Bridgeburg, two 5″ single stage, type CS pumps.
St. Thomas Water Works Pumping Station, St. Thomas, three 8″ 2 stage, type CSU pumps, each direct connected to 150 h.p. motors.

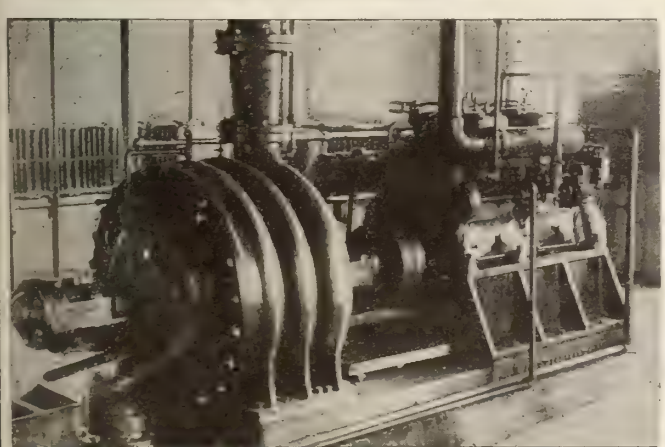
THE ENGINE of REFINEMENT
For the finest boats that float

What Emergency Power Do You Employ?

If your main steam powered pumps or generators are supported by a smaller steam powered unit for stand-by service; if your main electric pumps or generators are supported by a smaller electric unit—You are only half protected against breakdown.

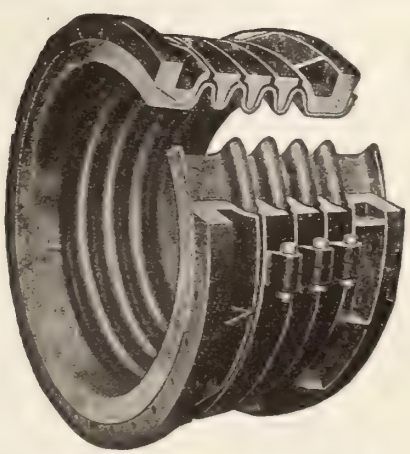


A high power Sterling gasoline engine—an independent source of power—will give you 100 per cent. protection.

These engines start like a high grade motor car and operate dependably at centrifugal pump and electric generator speeds.

CATALOGUE ON REQUEST.

Sterling Engine Co., Dept. C-4, Buffalo, N.Y. U.S.A.
12 to 300 H.P. Speeds 400 to 1400 R.P.M.



BADGER
SELF-EQUALIZING EXPANSION JOINTS

are the best joints for absorbing pipe expansion—Note the corrugations that expand and contract, thus preventing leakage.

Clearance Sale of High Grade Technical Books

FOR several years we have maintained a Technical Book Department, handling high-class books published by various well known publishers. For various reasons we have now decided to discontinue our Book Dept. and in order to clear out what stock we have on hand we offer the following books at prices considerably lower than the regular selling price. Each item represents high quality at bargain prices. These books will not last long—first come first served. This is a fine opportunity to add to your technical library.

Title of Book.	Name of Author.	Binding	Number of pages	Illustrated	Price
Electric Chemistry	G. W. Cravens	Cloth	132	Yes	$1.10
Hawkins Electric Dictionary (Best)	N. Hawkins	Leather	537	No	2.50
Electricity Simplified	T. O. Sloane	Cloth	172	Yes	.85
Electrical Motor	E. E. Burns	Cloth	197	Yes	1.25
Starting a Printing Office	R. C. Mallet and W. H. Jackson	Cloth	90	Yes	1.45
Half Tone Process	J. Verfasser	Cloth	378	Yes	....
Modern Printing Machinery	Wilson & Gray	Cloth	455	Yes	4.50
Manufacture of Paper	R. W. Sindall	Cloth	275	Yes	1.50
System for a Medium Size Printing Shop	C. V. Simmons	Paper	26	Yes	.50
Embossing	R. H. Dippy	Paper	12	No	.25
Patents, Inventors, Advisers	Marion & Marion	Cloth	170	Yes	.75
Machinists' Guide	Wm. Rogers .	Cloth	323	Yes	1.50
Mechanical Refrigeration	S. Sydney .	Cloth	70	Yes	1.25
*Stationary Engineers.	Is in sets of three volumes.				
Boiler Construction	F. B. Kleinhans	Cloth	422	Yes	2.50
Gas and Oil Engines	L. E. Brookes	Cloth	192	Yes	.85
Ford Car	V. W. Page	Cloth	288	Yes	....
New Catcehism of the Steam Engine	N. Hawkins	Cloth	429	Yes	1.50
Mechanical Arts Simplified	D. B. Dixon	Cloth	497	Yes	1.25
Setting Valves of Canadian-made Engines	G. C. Keith	Paper	31	Yes	.25
Change Gear Devices	O. E. Perrigo	Paper	81	Yes	1.25
Factory Power Costs	J. G. Branch	Paper	43	No	.75
The Field Engineer	Unable to find book in stock				1.50
Power Stations and Transmission	G. C. Shand	Cloth	84	Yes	.85
Liquid Air	T. O. Sloane	Cloth	365	Yes	2.10
New Guide Book to the Local Marine Board	C. M. Swainson	Cloth	545	Yes	1.30
Modern Machine Shop Tools	W. H. Van Dervoort	Cloth	552	Yes	3.00
Locomotive Catechism	R. Grimshaw	Cloth	432	Yes	1.50
Locomotive Breakdowns	G. L. Powers	Cloth	244	Yes	1.25
Modern Ironmonger		Cloth	341	Yes	1.00
Gas Engine Troubles	J. B. Rathbun	Cloth	448	Yes	1.00
Combustion of Coal and Prevention of Smoke	Wm. M. Barr	Cloth	347	Yes	1.25
How to Run Gasoline Engines	C. Von Culin	Paper	144	Yes	.50
Engineers' Library	W. H. Wakeman	Paper	Different No. in each	Some are	.25
Elements of Machine Design	J. H. Barr	Cloth	446	Yes	2.00
Hawkin's Indicator	N. Hawkins	Cloth	73	Yes	.75
Gas Engine Construction	Parcell & Weed	Cloth	304	Yes	2.00
Aids to Engineers Examinations	N. Hawkins	Cloth	222	No	1.50
Mechanism of Mechanical Movements	Unable to find book in stock				2.00
Pattern Making	Ritchey & Monroe	Leather	222	Yes	1.25
Machine Design	E. L. Wallace	Cloth	157	Yes	1.25
Foundry Work	B. L. Gray	Cloth	196	Yes	1.25
Forging	J. Jernberg	Cloth	131	Yes	1.25
Tool Making	E. R. Markham	Leather	288	Yes	2.00

***These books are in sets of 3 volumes to a set. There are eight sets in stock. The price of which are $4.50 per copy of $12.50 per set.**

Above prices includes postage. Cash must accompany order as at the reduced prices quoted accounts cannot be opened. Remit by express or P.O. money order or by registered letter.

BOILER LININGS AND DOOR ARCHES

We specialize in all kinds of Power Plant Brick Work.

Boiler setting, furnace building and oven work are our specialties. Our engineers are at your service; call on them at any time for any information you may require —without obligation to you.

We are able to supply refractory linings for all purposes. If we have not the size and shape you desire in stock, we will make it to order.

DART UNIONS

Never Loosen Up and Leak

By using Dart Unions you can make connections easily and quickly—without bother—whether pipes are in or out of alignment.

There'll be no upkeep cost, no replacement cost—and no loss from leaks.

Farnsworth Equipment Reduces Coal Expenses to a Minimum

Big plants, all over the world, are reducing their coal bills. Some 20% or more! Farnsworth Closed Condensation Systems are not an experiment. Their use has **proven** more economical in the long run. Experience shows that in the majority of cases the equipment pays for itself in from three to six months.

New Canadian Factory

The Canadian Farnsworth Company, engineers and manufacturers of condensation pumps, automatic boiler feeders, return steam traps, all of the duplex type, and general steam utilities, have opened and are now operating their new factory at 1—24 Hillingdon Ave., Toronto. These lines were formerly manufactured by the Canadian Fairbanks-Morse Company.

Send for copies of bulletin on Steam and Condensation; they are interesting and instructive.

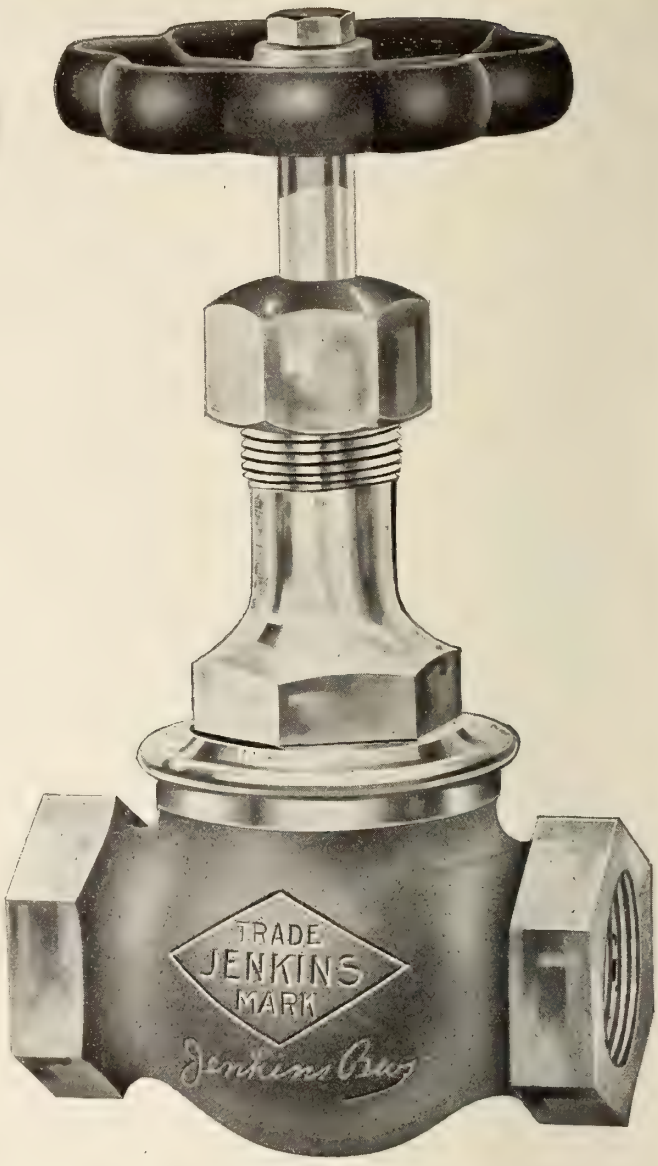
Jenkins Bros

are imitated but never equalled



With more than half a century's record of satisfactory service behind them, it is but natural that Jenkins' Valves should have a host of imitators.

But the imitation is confined to *Appearance* only. The *Service* that Jenkins' Valves give, and upon which their enviable reputation has been built up, can only be secured from the genuine Jenkins' Valve with the Diamond Trade Mark cast on the body.

It will pay you, therefore, to look for this trade mark when selecting valves for every condition of usage. Whether the valves are to be used in connection with a battery of Boilers, a heating plant or a plumbing installation, Jenkins' Diamond Trade Mark Valves will give dependable service.

Catalog No. 8, picturing and describing the complete Jenkins' line, will be mailed you on request—free of charge.

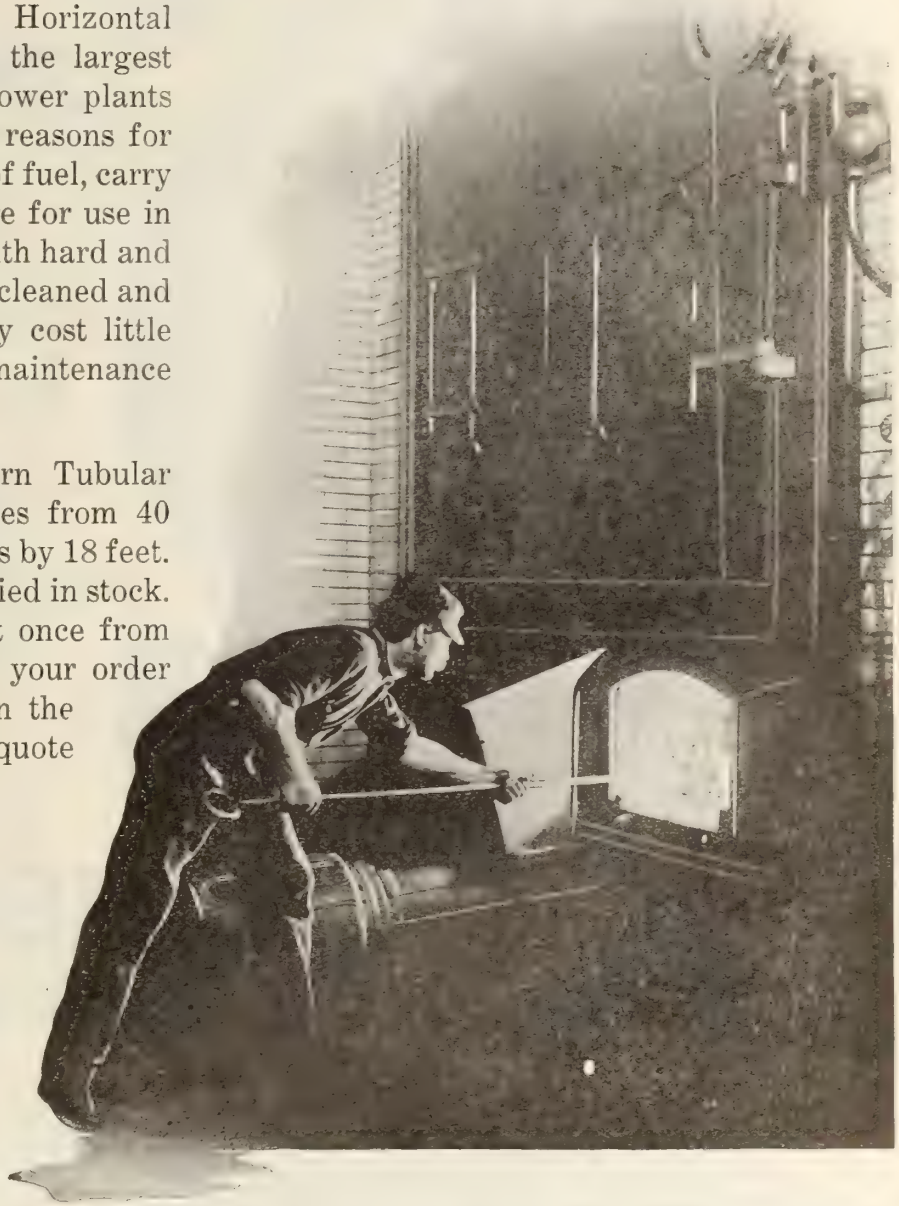
BOILERS

FOR POWER AND HEATING PURPOSES

You will find Waterous Horizontal Return Tubular Boilers in the largest industrial and municipal power plants in the country. There are reasons for this. They are economical of fuel, carry a big reserve steam pressure for use in emergencies, can be used with hard and dirty water, and are readily cleaned and easily taken care of. They cost little new; their upkeep and maintenance expense is negligible.

Waterous Horizontal Return Tubular Boilers are built in all sizes from 40 inches by 10 feet to 72 inches by 18 feet. Most standard sizes are carried in stock. If we cannot supply you at once from our yards we can turn out your order for you in quick time. On the next boiler you need let us quote you prices and delivery.



Boilers in Stock

1—54 x 14 Horizontal

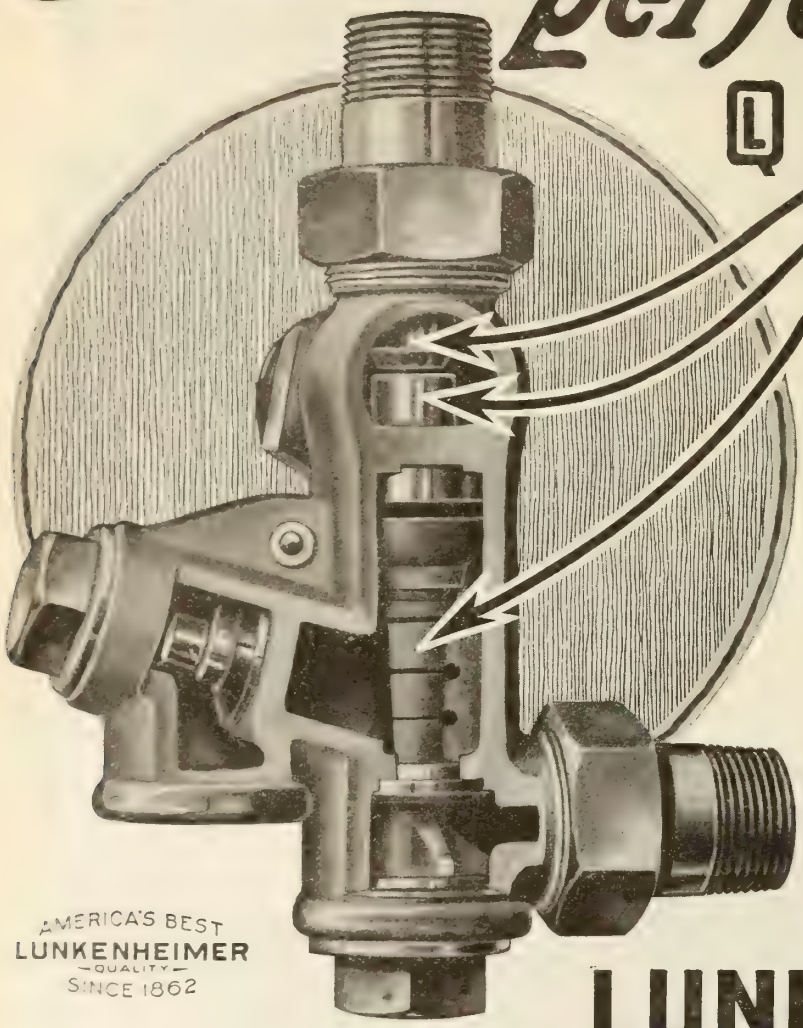
4—66 x 16 "
14—72 x 18 "
2—40 H. P. Locomotive

Waterous

BRANTFORD, ONTARIO, CANADA

Consistent performance



The correct design of the tubes and the large areas through the body of

LUNKENHEIMER
AUTOMATIC INJECTORS

account for the excellent service which they give. They deliver more water per pound of steam, have full capacity at higher steam pressure, and their capacity is diminished in a lesser degree by long lifts and hot feed water than any other.

The tubes being made of a *special hard bronze,* resist the severe erosive action of the saturated flow at high velocity, and the Lunkenheimer design of "spill" eliminates the uneven wear of the combining tube which is the cause of most injector trouble.

Lunkenheimer Injectors are highly efficient, reliable and economical boiler feeders. Their wide range of operation, instantaneous re-starting after a temporary interruption of the steam or water supply, their durability and the interchangeability of all parts, merit consideration and recommend their installation.

Specify LUNKENHEIMER and insist on having the genuine.

New Truths and Old Fallacies

Fusibility of Alloys—*Continued*

Binary alloys are classed as solid compounds, but in trinary and quarternary alloys only two of the elements are said to form a compound, as, for instance, in a tin-lead-antimony combination only the tin and antimony form the compound. Other characteristics in this connection will be discussed further on.

We give below the principal ingredients used in babbitt metals, and the approximate melting points, as we shall deal with these figures as we progress, viz:

Tin, 446° Fahrenheit; Lead, 619° Fahrenheit; Antimony, 1166° Fahrenheit; Copper, 1992° Fahrenheit. It is axiomatic that good conditions will favor an inferior metal and adverse conditions militate against a good metal; hence it is not always possible to form an off-hand opinion as to the relative values of babbitts in actual service as careful comparative tests and records are generally necessary to reach a conclusion. In laboratory tests, however, comparative values can be determined quickly and accurately as maximum stresses can be applied and both water and oil lubrication used.

Genuine Babbitt was the first white metal alloy used for lining bearings and derived its name from Isaac Babbitt, who first used it. He did not patent the mixture and was even uncertain as to its being the best, hence his patent merely covered the process of soldering alloy to the shell. However, his composition is about as good as can be made, and was used exclusively until lead base alloys appeared. Babbitt users naturally favored Genuine through force of habit and inherited custom and therefore when Magnolia was first introduced there was considerable opposition and mistrust regarding it.

Coal Crisis At Hand!

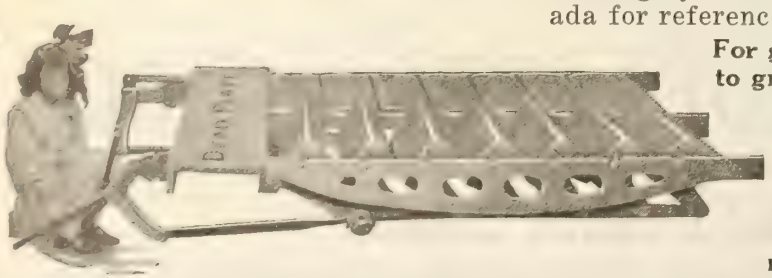
Nonpareil Grates Will Help You Meet it

Coal prices still advance. The demand is greater than the supply. The economical way to meet it is to let Nonpareil Grates reduce your coal bill 10 per cent.

A test will convince you—Nonpareil Shaking and Dumping Grates may be put under any kind of a boiler for a test period of thirty days. Should they fail to save 10 per cent. in fuel bill by better combustion, or prove unsatisfactory in any way, they may be removed and shipped back to us—we pay the freight. **Remember, Nonpareil Grates burn any fuel with heat in it.**

Firebrick Work

You know you are safe when "Safety First" Sexton tackles your firebrick work. Sexton has a reputation for building in boilers and doing general repairs, quickly and thoroughly. Many of the larger plants throughout Canada for reference.



For grate bars of all kinds and repairs to grates of all kinds see Sexton.

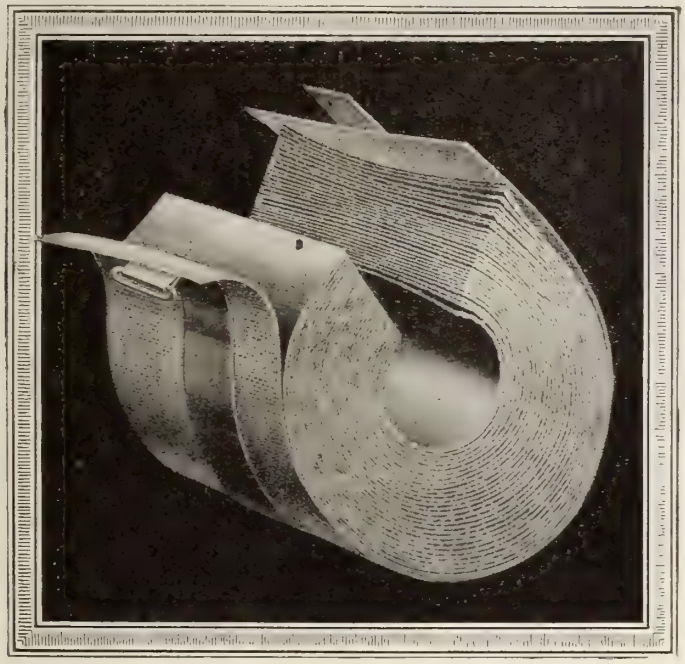
Asbesto-Sponge



SOMETHING NEW? Hardly! For instance, here's a case that can probably be equaled—maybe excelled—but only by another lot of Johns-Manville Asbesto-Sponge Felted Pipe Covering.

Back in the days when Cleveland was President; when Cuba was struggling to throw off the Spanish yoke; before automobiles were taken seriously by more than a few people and when aeroplanes were said to be "impossible," a certain firm put some Johns-Manville Asbesto-Sponge Felted Covering on its steam lines.

Twenty-two years later that Asbesto-Sponge Felted Covering was still giving the best of insulation service, but the piping had to be dismantled because of change in the layout.

—And after 22 years of hard service this Johns-Manville Asbesto-Sponge Felted Insulation had retained its original properties—and its insulation value was unimpaired.

So when we say Johns-Manville Asbesto-Sponge Felted is the best commercial insulation known, we're not talking about something new. We're telling you about a material of known value which has withstood the hard test of years of efficient service.

In our booklet there are more facts of value. Send for it.

LEONARD

Let Riley Stokers Reduce Your Costs

Riley Stokers are always on the job—you can rely on them to be at work every day. They are tireless—working all hours of the day and night—without complaint.

Industrial plants can cut their operating costs to a minimum by using Riley Underfeed Stokers. Consider the following facts :—

EFFICIENCY—Boiler tests on Riley Stokers have shown over-all efficiencies of 80% and higher.

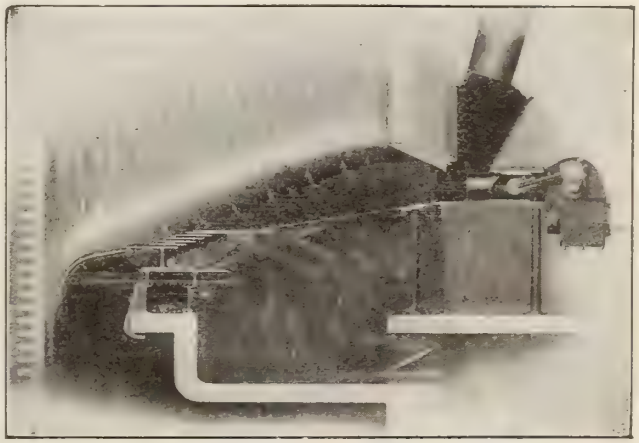
LABOR SAVING—One or two men can replace ten or twelve required for hand firing. Continuous, automatic discharge of ashes means elimination of drudgery in fire cleaning. Labor for ash handling in a well-laid-out plant is negligible.

COMPLETE COMBUSTION — The underfeed method and moving grates intimately mix the proper amount of air and coal, giving perfect combustion.

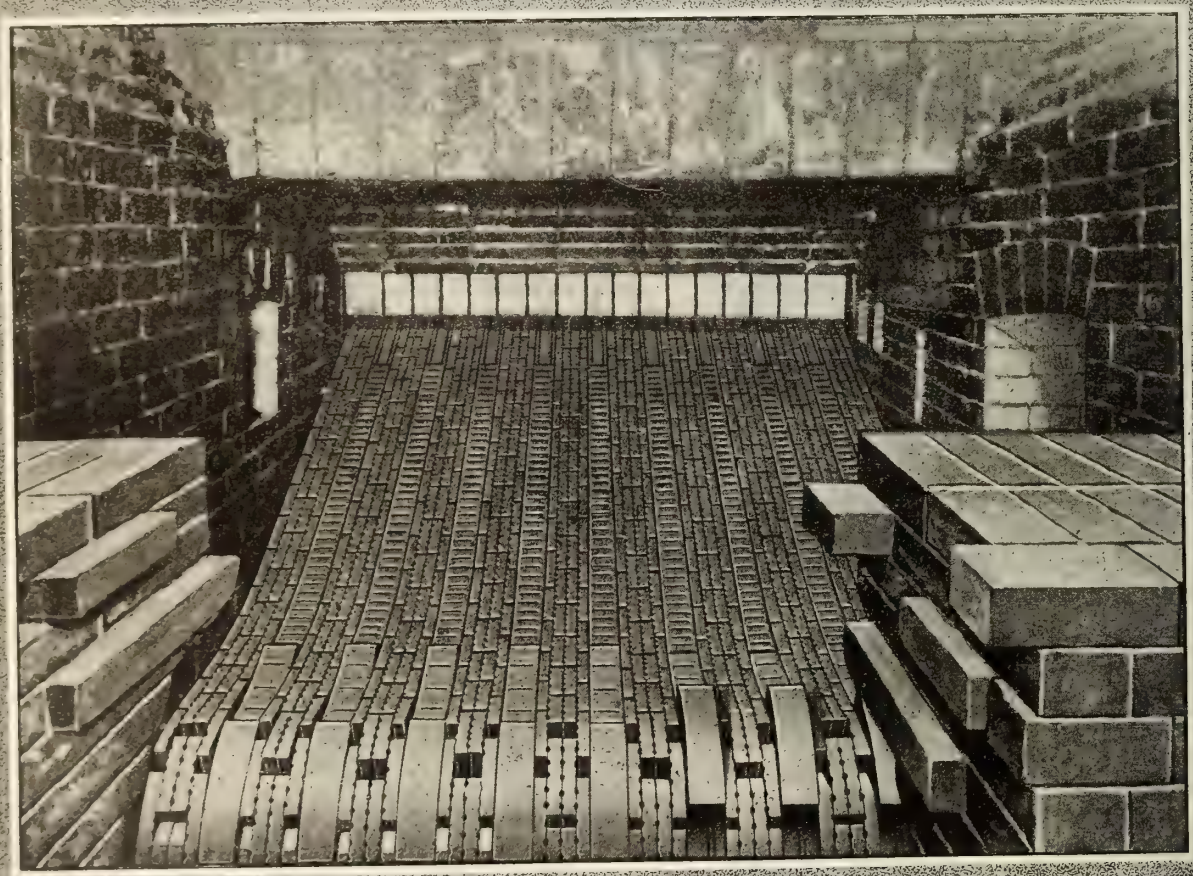
Catalog HR-7 sent on request.

For information on the Murphy Automatic Furnace for small plants, see last month's advertisement, or send for Murphy's catalog HM-7.

Sanford Riley Stoker Co.
Worcester, Mass.



THE
STOWE STOKER
Employing Mechanical Draft



LACLEDE
A BUSINESS INSTITUTION

Forced-Draft, Conveyor Feed

—*The Scientifically-Correct Stoker Principle*

The engineering profession in general has always admitted the fundamental superiority of progressive feeding, or more properly, the *conveyor* feeding principle. What shortcomings this principle may have had are now entirely overcome by the application of forced draft.

In this engineering triumph—*the forced-draft, conveyor-feed* stoker—capacities of 300% are an every-day occurrence. Economies after deducting for auxiliaries slightly *excel* those of any other forced-draft type. Flexibility sufficient for all practical purposes is obtainable. Coking coal may be burned successfully.

With these fundamental facts demonstrated, it it obvious that such things as the ease in handling, absolutely automatic operation, absence of clinker and perfection of ash disposal put this type of stoker unquestionably in the foreground.

THE STOWE STOKER is destined to dominate this field because:

(1) A single Stowe Stoker can be used for units up to 1500 H. P., thus doing away with the center fire wall.

(2) Graduated air spaces are substituted for the complicated arrangement of various air pressure compartments.

(3) Drippage, instead of clogging air passages, falls into a pit provided for that purpose.

(4) It is the *only* conveyor feed built on a decided incline and therefore excels in strong ignition temperatures.

(5) It is the *only* conveyor feed that holds the nearly spent fuel back on the grate until every bit of combustible is consumed.

(6) There are no air ducts in the firing aisle.

In selecting your forced-draft, conveyor-feed stoker, keep in mind these outstanding advantages of the Stowe Stoker.

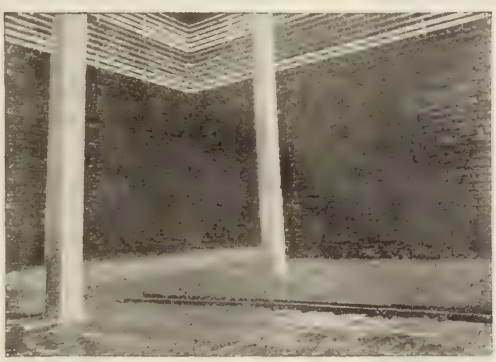
Balancing an Unbalanced Business

Because of the wide variation in the demand for ice, a great many manufacturers conclude that they must run their plants under a heavy overload during the warm months, and then let them lie practically idle during the slack season. As a result, these plants seldom produce more than 50% of their annual capacity, and naturally the large overhead expense adds materially to the cost of production.

Take the case of the City Ice Company, Lexington, Ky., for instance. In 1911, when their plant was operated in this manner, the output was only 43.9% of its yearly capacity, the company was unable to handle the summer demand, and the manufacturing cost averaged $2.50 per ton. In 1914, however, they provided a 5,000-ton ice storage completely insulated with Nonpareil Corkboard Insulation. By filling it during the off season and disposing of the accumulated ice during hot weather, the plant was able to operate under a nearly constant load the year round. And during the first twelve months the storage house was in use, the company operated at 91.3% of its yearly capacity, while the manufacturing cost was reduced to less than 45c per ton.



The walls of the ice storage of the Peoples' Ice Company, Wichita Falls, Texas, are insulated with Nonpareil Corkboard Insulation, mastic finish.

If your manufacturing costs are high, and if you can't meet the summer demand, an ice storage is probably what you need. It would be a good idea to make your plans now so that you can have your storage in time for next year's business.

Armstrong Cork & Insulation Company, 504 McGill Building, Montreal, Quebec, Canada

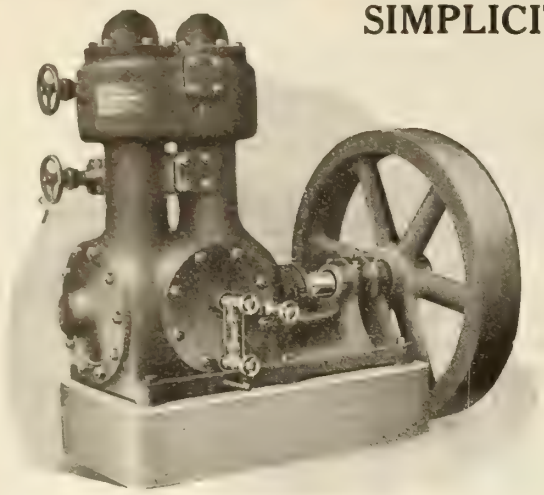
Also manufacturers of Nonpareil Cork Covering for brine, ammonia and ice water lines; Nonpareil Insulating Brick for boiler settings; Nonpareil High Pressure Covering for steam lines and Circle A Cork Brick for cold storage room floors.

Nonpareil Corkboard Insulation

For Ice Storages and Other Cold Storage Rooms

York Enclosed Refrigerating Machines

SIMPLICITY—ECONOMY



After operating one of our Enclosed Machines for several years, one of our customers writes us that he has not spent one cent on it except for oil, and is still using the original charge of ammonia. This is a common experience among users of these Machines.

Simplicity of design and accuracy of construction permits them to be operated successfully by employees who, prior to the installation of these machines, never had any experience in operating one.

If you are finding the present scarcity of ice a burden to your business here is a simple and safe method of relief, and besides MECHANICAL REFRIGERATION pays good dividends on the investment.

Write us for information and prices.

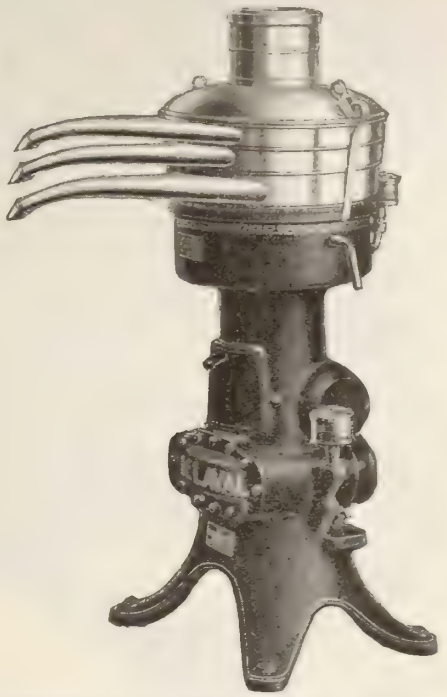
Formerly Jones Cold Store Door Co. HAGERSTOWN, MD., U.S.A.

The DE LAVAL
Centrifugal
Oil Purifier

The De Laval Centrifugal Oil Purifier is a new and modern means of recovering oil which, through use, has become unfit and dangerous to use.

The Method is simple, continuous and economical in operation and restores the oils to their original usefulness.

The Oil Purifiers are built in three sizes, each size in either electric, belt or direct steam turbine drive. They are used for purifying many kinds of oils in various industries.



De Laval Oil Purifier—Turbine Driven

Lubricating Oil

The De Laval Method removes water, dust, grit and metal particles from used lubricating oil. The absence of these impurities makes the wearing parts last longer, reduces loss of power, saves the machinery, and eliminates the dangers of a clogged oil system.

Cutting Oils

A résumé of the results obtained in several machine shops using the De Laval Method of reclaiming cutting oils shows:

A net saving per year of 20 to 50 per cent in oil consumption, better finish on work, increased production of machines, 15 to 60 per cent longer life of cutting edges of tools, and greatly reduces the dangers of septic poisoning.

In reclaiming oil from soda-wash it saves oil and soda-wash, which previously were wasted.

Hardening Oils

The De Laval Method eliminates carbon and scale from drawing oil, thereby insuring more even and more effective hardening. It also reclaims the oil which heretofore was thrown away with the impurities.

The De Laval Method does the same for quenching oil and eliminates the clogging of the oil system, with its accompanying danger and delay.

Fuel Oils

The De Laval Method removes grit, dirt, carbon and water from fuel oils used in Diesel type engines. In this way the delay and danger caused by grit in pumps, valves and other working parts are practically eliminated.

Write to nearest De Laval office for Oil Purification Bulletin No. 100, which describes the benefits and savings in detail

A complete experimental department is maintained for working out the problems of our customers by means of centrifugal processes

GAS TIGHT BAFFLES

Vertical—Horizontal—Inclined. Any shape, size, slope or angle. Monolithic and Permanent.

The one-piece idea is the logical solution of the baffle problem.

Perfect fitting, gas tight baffles of any size, shape or angle are easily moulded into place with.

BETSON'S PLASTIC FIRE BRICK

In the construction of baffles of Betson's Plastic Fire Brick, the material is packed solidly between the tubes, and, therefore, conforms exactly to them. These baffles always fit tightly, when the boiler is steaming, because the material sets when the tubes are hot. When the boiler is cold the tubes contract and draw away, making tube renewals easy without disturbing the baffles.

Betson Baffles may readily be placed at the proper angles for meeting the new idea of gradually reduced Gas passes.

Send for instructive pamphlet. You should also have our catalog on complete furnace linings. Quotations given and questions cheerfully answered.

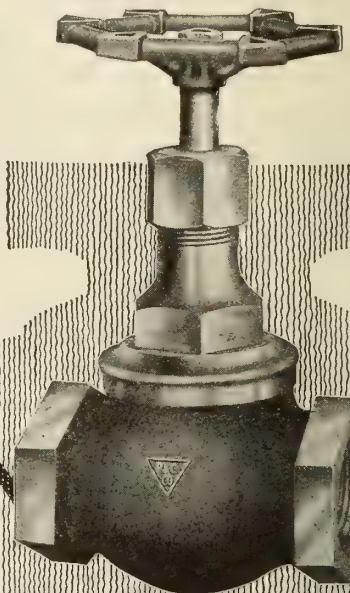
Why Pay 90% More for Your Valves ?

Every time you replace a worn valve with a new one, you are paying 90% *more* for that new valve than it would cost to renew a Pratt & Cady Renewable Globe or Gate Valve.

That may mean only a dollar or two per valve, but figure the total cost per year!



PRATT & CADY RENEWABLE VALVES

can be made as good as new, when worn, at about 10% of the original cost of the valve.

This takes but a few minutes. The valve doesn't even have to be removed from pipe line.

Due to this renewable feature and their rugged construction, a P & C Renewable will outwear a great many ordinary valves.

No matter for what purpose you require a valve, there's a P & C made specially to meet the condition. We should like to send you our booklet.

REES RoTURBo

Rotary Jet Condensers and Vacuum PUMPS

Sole Canadian Manufacturers

The REES-RoTURBo products are widely used in Great Britain and United States and are recognized as the very latest development in this class of apparatus, which include REES-RoTURBo Patent Pressure Chamber Self-Regulating Pumps, Rotary Jet Condensers and Rotary Vacuum Air Pumps.

The Rotary Jet Condenser is used in connection with steam turbines and reciprocating engines. It is particularly adaptable to sugar and salt boiling plants, etc. The Rotary High Vacuum Air Pump is identical in principle with the Jet Condenser and possesses similar advantages. **Made in Canada by the G. & McC. Co. only.**

The engineering profession of Canada is well acquainted with the **quality** in construction that typifies all G. & McC. Co. products —this **quality** is thoroughly maintained in REES-RoTURBo Rotary Jet Condensers and Vacuum Pumps.

Power Plant Features of the Canadian Ford Co.

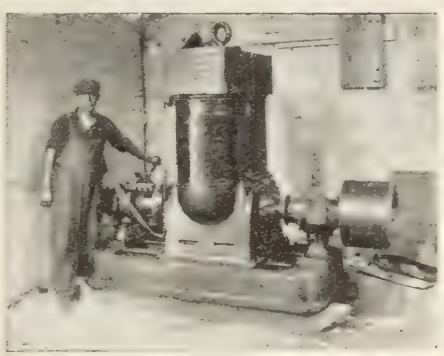
The Power Plant of the Ford Motor Company of Canada Is Interesting on Account of Its Size and Many Novel Features Incorporated in Its Design

By W. F. SUTHERLAND

THE story of the Ford car has often been told, and the manner in which the vision of Henry Ford became a reality is well-known to everyone. The Ford shops and Ford methods, too, have become well-known, and originality and engineering skill have made them unique in many respects. Particularly is this true in the generation of the power necessary for the plants of both the Ford Motor Company of Detroit and of the Ford Motor Company of Canada, Ltd., at Ford, Ont.

This article deals with some of the many interesting features of the latter plant, and before entering upon a description of the engineering features of it, it may be well to say that the Ford Motor Company of Canada, Ltd., is a strictly Canadian organization throughout, and in addition to supplying the domestic demand it exports to practically every one of the British Dominions and possessions. The car made by the Canadian company at Ford City is not merely an assembled product, and "made in Canada" in this case means not merely an aggregation of small parts assembled here, but actually manufactured. Less than $20 worth of imported parts are used in its fabrication. From the raw material to the finished product every step in the making of the car is done in Canada, thus necessitating the employment of four thousand men.

The original power plant first used at Ford City was on quite a modest scale as will be seen from one of the illustrations. A 75 horsepower Edison bipolar machine, of the type familiar in the earlier days of the electrical industry, furnished the power by which



ORIGINAL POWER PLANT.

the shops were run. From this modest beginning to the present plant in the short space of fourteen years is quite a step, and the advances made in engineering practice incorporated in the present plant are on a comparative scale to the horse-power generated formerly and today. Many of the features of design seen in the present power plant are original with Ford engineers, and throughout the economical production of power has been the chief desideratum.

The present plant of the Canadian company may be said to consist of two sections, an older one in which moderate size units were installed and the latter one containing the 3,000 kw. "Gasteam" unit only placed in complete operation during the latter part of 1919. Several factors held sway in determining the type of prime mover installed. The superior thermal efficiency of the gas engine, the need of gas for shop purposes, the reliability of the steam engine, and the necessity for some means of shop heating were all determining factors which led to the selection of a combination steam and gas unit. A very high overall efficiency also resulted from this type of engine since each prime mover supplemented the other.

With both gas and steam units in operation the power plant includes boiler room and producer gas plant, and it may be well to treat these first, passing in turn to the engine room and other plant features.

The Boiler Room

Six Badenhausen boilers are installed, four of 380 h.p. and two of 500 h.p. The smaller boilers are equipped with five retort Taylor stokers, and the larger with seven retort stokers of similar make. The stokers are driven through Link Belt Co. silent chain drive by variable speed reliance motor or in emergeny by a 7 x 7 inch Troy vertical steam engine. The 500 h.p. units are provided with superheafers designed to give 200° superheat. The 380 h.p. boilers are not provided with super-heaters, but like the 500 h.p. boilers have some superheating surface integral with the boilers which gives about 20 degrees to 30 degrees of superheat. The Taylor stokers on both types of settings are fitted with extension grate and dump plates but without clinker grinders. The boilers and stokers are designed for 75 per cent. combined effiiency.

The draft pressure required to burn 55.7 lbs. of coal per sq. ft. per hour on the grates is in the neighborhood of 1½ to 2 inches static pressure at the tuyeres. The forced draft fans are of the Buffalo turbo-conoidal double inlet type. Two

are installed and each have a capacity of 50,000 cu. ft. per min. at 2 in. static pressure. One of them is driven by a 50 h.p. motor and the other by a 75 h.p. steam turbine.

Diamond soot blowers are installed. The blow-off piping is fitted with a Johnson gate valve and a Simplex blow-off valve to each boiler. The boilers were formerly equipped for the burning of natural gas but on the failure of the supply this source of heat is no longer used.

The ashes are removed at the rear of the boiler settings by an American steam jet ash conveyor to an overheat tank. The waste gases are exhausted by means of a Weiderholdt concrete chimney finished with 1 inch tile outside and inside. The chimney is lined with fire-brick to ten feet above the breeching, and this lining has an inside diameter of 10 feet, while the chimney at the base is 14 ft. 5¼ in. outside diameter by 12 ft. 9¼ in. inside. It is 165 feet high.

FIRING AISLE SHOWING BOILER STOKERS AND PRODUCERS.

Coal Handling

Coal is delivered from railroad cars to a track hopper located in a coal tower exterior to the plant. An 18 in. apron conveyor carries it to the crusher from which it reaches the overhead bunker through a continuous elevator pick bucket delivering on to a belt conveyor provided with two automatic trippers. The capacity of the equipment is forty tons per hour. The conveyors were supplied by the Link-Belt Company, while the crusher of the hammer type was installed by the Williams Patent Crusher and Pulverizer Company.

The use of both producers and boilers necessitates the sizing of the coal since the producers work best with 1 in. to 3 inch. lump coal while the stokers use the finer fuel. The sorting into two sizes is automatically performed by a screen attached to the first tripper. The coarse coal can be discharged directly from the screen on the first tripper into the producer bunker while the fine is put back onto the belt and goes to the second tripper to be discharged into the boiler bunker at that point, or vice versa, the fine can be discharged by the first tripper into the boiler bunker and the coarse put back onto the belt and discharged by the second tripper into the producer bunker. It is thus possible to discharge either fine or coarse into any part of the bunkers, irrespective of which part of the bunker is being supplied by the other tripper.

Boiler Feed

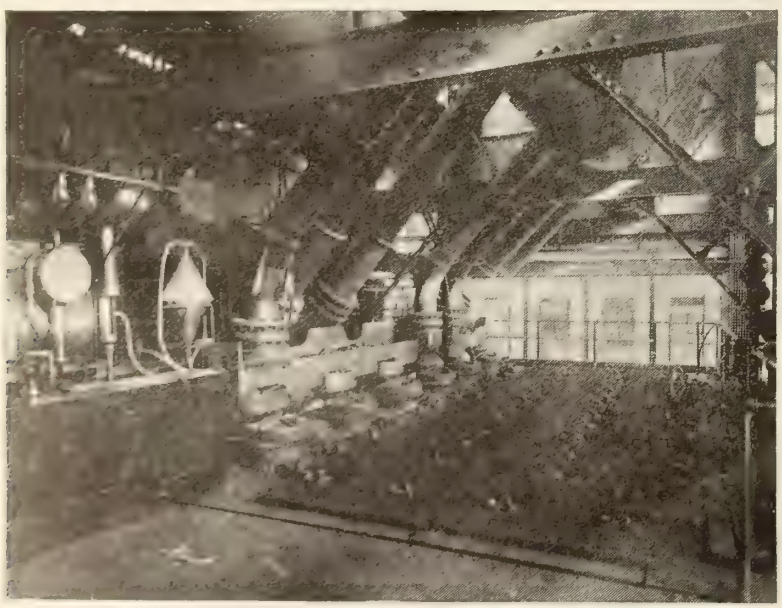
The main boiler feed line is located at the rear of the boilers and is fed from a Swartout open feed water heater of 3,000 h.p. capacity by means of either of two pumps. The first of these is a 3 in. four stage Rees Roturbo pump having a capacity of 250 gallons per minute at 250 lb. pressure. It is driven by a General Electric single-stage turbine of the Curtiss type, at 3,000 revs. per min. The other is an eight stage pump of the same make and is driven by a Westinghouse d.c. motor at a speed of 1,900 revs. per min. The turbine-driven pump is fitted with speed-limiting device and an automatic pressure control governor. The boilers are equipped with Cope's feed-water regulators.

The feed water heater receives all the exhaust steam from the various plant auxiliaries and all oil free condensate and such gas engine cooling water as is not required for hot factory service. Feed water is treated to precipitate all scale forming solids in the heater.

Factory Heating

The factory is heated by a force circulating hot water system, the water being circulated through the engine condensers. Live steam is used to make up the small difference between what is obtainable from the condenser in use and the existing load. The outgoing temperature is maintained at the proper point to supply the required amount of heat, dependent upon the outside temperature.

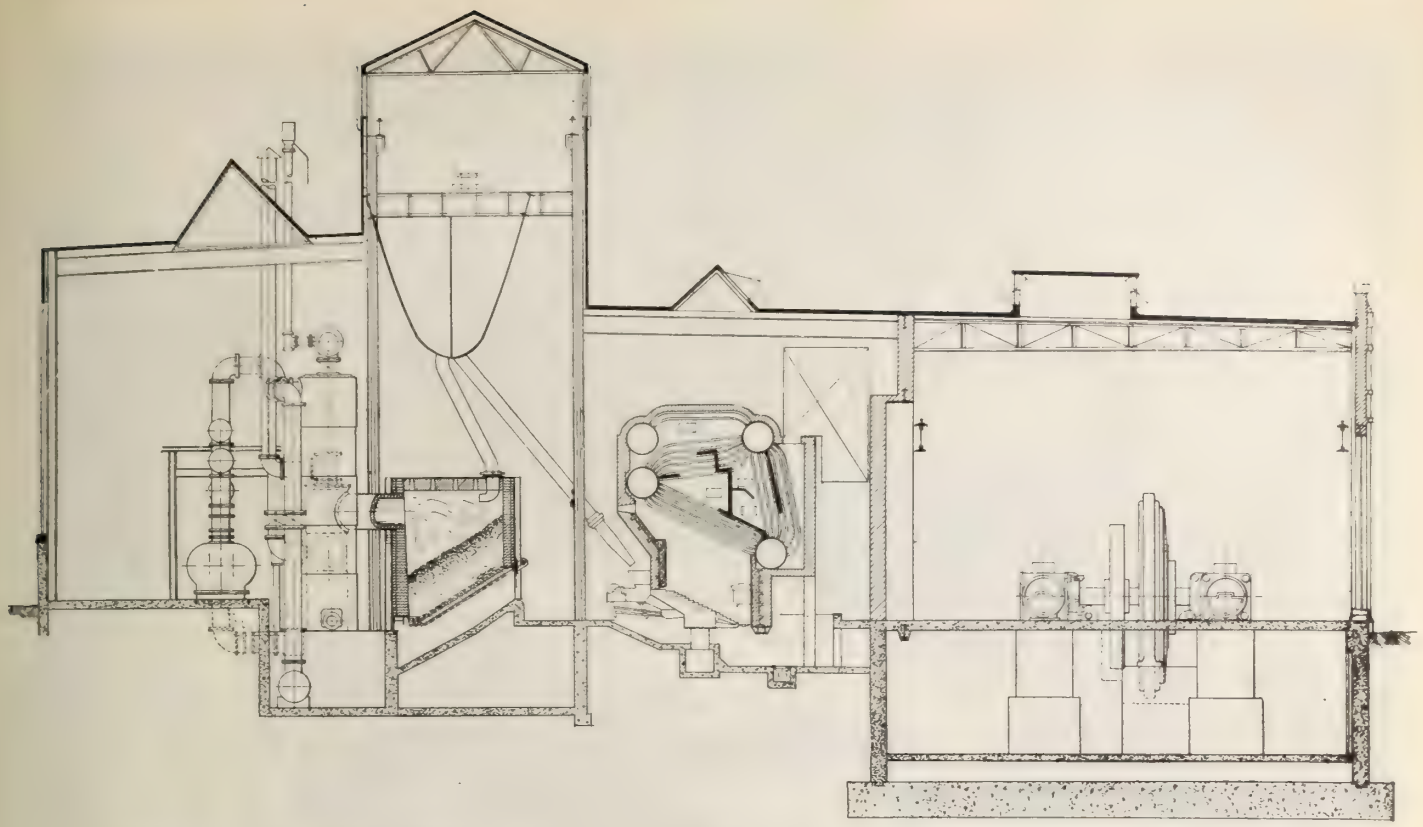
For zero weather it is necessary to maintain an outgoing water temperature of 190 degrees fahr. while delivering 1,000 g.p.m. The return water temperature under these conditions will be about 160 deegrees fahr. Two circulating pumps are provided of 8 inch. size, either one of whom will supply the above requirements, the other being a reserve unit. One pump is driven by a 15 h.p. General Electric turbine of 1,440 r.p.m., the other by a Canadian Westinghouse motor. The condensate from the live steam heater flows into a receiver, from which it is pumped by a Burnham pump direct to the feed-water heater.



TOP OF GAS PRODUCERS SHOWING COAL DISTRIBUTORS AND GAS ANALYSIS APPARATUS.

Gas Producer Plant

At one time the natural gas fields of Western Ontario were capable of supply-



SECTIONAL ELEVATION THROUGH POWER-PLANT SHOWING PRODUCER PLANT, BOILERS AND GASTEAM UNIT.

ing a very cheap fuel for industrial and heating purposes. With their approaching exhaustion this condition has changed and industrial plants are no longer able to use natural gas. At this particular plant natural gas was used, not only under the boilers but also in the gas engines. Since this fuel is no longer available gas producers have been installed, and in their construction and operation much of interest is seen.

Three Smith suction gas producers are installed at this plant, being located immediately opposite the boilers and fed from their own portion of the common bunker. Each producer is rated to gasify 50 tons of coal per day of twenty-four hours, and is built up of six sections. An inclined grate is used which has an inclination of 35 degrees from the horizontal. Each producer has 270 sq. ft. of grate surface and at the bottom of the grates heavy clinker bars are provided for the crushing and passing through to the ashpit all clinker that settles through the fuel bed to the grate.

Coal coming from the bunkers above through chutes is automatically fed into the producer by means of a mechanical stoker designed to admit the charging of coal without admitting air. This mechanism may be seen in one of the illustrations.

The gas leaves the producer at about 1,110 deg. fahr. and is cooled and washed in a primary cooling tower by means of water sprays, the water being supplied at a pressure of 20 pounds.

The gases are drawn through the primary coolers and from the producers by means of Connelsville gas exhausters, one to each producer. Each exhauster has a rated displacement of 6,000 cub. ft. of gas per min. and is driven by a twin direct connected 11 x 24 in. high-speed Corliss engines of Hooven Owens Rentschle make. These exhausters boost the pressure to about 3 pounds. The gas is then forced through Smith tar extracters which consist of sun glass wool diaphragms suitably housed. The tar-laden gas is driven at high velocity through these spun glass wool diaphragms (about 1½ pound of glass wool to each extractor) and an agglomeration of tar particles takes place until they are of sufficient size to drop out of the gas by gravity. The life of the sun glass wool is from two to three months, depending on the quality of the wool used and the care taken in packing it in the diaphragm. The tar flows from the tar extractors to a tank 36 in. in diameter located in the basement. After leaving the tar extractors the gas then passes through a secondary cooler in which it is cooled as low as the temperature of the river water will permit, this is done to remove as much moisture as possible.

The water from the primary cooler is sent to a tar settling tank where the tar settles out and is piped to the main low-pressure gas header. The tar which separates out in the tar extractors likewise is piped to this header. From here the tar is drained into a small tank at a lower level, and when this is full, steam is admitted and the contents elevated to another tank at a higher level than the tops of the gas producers. From this point the tar flows to the atomizers in the producers by gravity. The sprayer, by means of which the tar is atomized and distributed over the fuel bed is made by placing a ⅜ steam pipe inside a 1 in. tar pipe. The ends are reduced in area and are approximately flush with bottom of the top lining of the producer.

The successful disposal of the tar is no mean accomplishment and is a problem which has bothered many gas plant operators. No little credit is due the engineers of the Ford Motor Company, and Mr. H. F. Smith, of the Smith Gas Engineering Company for the successful working out of the system at present in use.

The spraying or vaporization of the tar in the producer has an appreciable effect on the heat value of the gas, which shows a gain of anywhere from 10 to 15 B.t.u. per foot. Due to a slight increase in the percentage of methane.

A low-pressure steam line is carried inside the main tar header and this serves to keep the temperature of the tar at about 160 deg. Fahr., so that it flows very nicely through sight feed flows.

The operation of a producer plant is an art in itself. Three firemen are required for each producer, and by means of ⅞ steel bars from 6 to 19 feet long they keep the fuel-bed compact and in good condition. In particular they watch for holes and other unevenness which may develop in the bed to the detriment of the gas being made. The depth of fuel bed averages about 5 feet on high side of the grate and 7 feet at the other end.

The exhaust steam from the blower engines is used to saturate the air blast to the producers and an intermittent acting thermostatic valve is used to automatically control the steam supply and maintain a blast temperature of

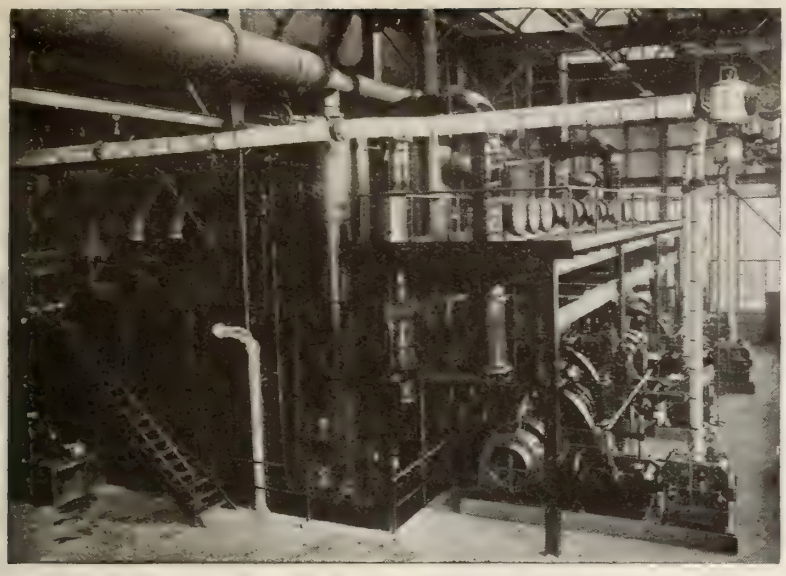
EARLIER PORTION OF PLANT SHOWING GAS ENGINES AND SMALLER GAS-STEAM UNIT.



GAS PRODUCER EQUIPMENT WITH BLOWERS AND ENGINES.

between 140 deg. and 150 deg. fahr. More than half of the exhaust steam from the source is thus utilized. The balance goes to feed water heating.

With a temperature of blast below 140 deg., clinker troubles are apt to arise, and with a greater temperature than 150 deg. the percentage of carbon dioxide increases to the detriment of the quality of the gas.

A gas testing cabinet forms part of the plant and is shown in an illustration herewith. The complete unit was supplied by the Smith Gas Engineering Company, and by its use a very accurate control can be had of the quality of gas.

Large Gasteam Unit

The large gasteam engine installed in the Canadian power plant is similar to those in the plant of the American Company at Highland Park, Michigan. The unit consists of a horizontal tandem compound steam engine together with a two-cylinder tandem gas engine, both driving through a common shaft a 3,000 kw. direct-current generator at 80 revs. per mm. The generator delivers direct current at 250 volts and at full load rating has a capacity of 12,000 amperes. It is compound wound.

The steam side as has been mentioned is tandem compound with 30 in. h.p., 60 in. l.p. cylinders, and 72 in. stroke.

The gas engine unit works on the four-cycle principle, employs make and break ignition, and has two double-acting cylinders, each of 42 in. diameter by 72 in. stroke; the valves are 12 in. in diameter and the piston rod 13 in., the latter made hollow for water cooling.

The high pressure steam cylinder is equipped with poppet valves in order to permit of the use of superheated steam at a high temperature, while the low pressure cylinder is equipped with Corliss valves. The exhaust steam leaving the h.p. cylinder passes through a reheater, through which a major portion of the exhaust gases from the gas engine are circulated. A small portion of these gases is circulated through the jackets of both the high pressure cylinder. A surface condenser of 4,900 sq. ft. area and built by the Wheeler Condenser and Engineering Company, is installed and is served by an 18 x 12 in. motor-driven Edwards wet air pump, together with the usual motor-driven circulating pump, which draws its supply from the river. The circulating water at the present time is returned to the river. It may at some future date be utilized for heating utilities when the heating load reaches such proportions.

An interesting feature in connection with the design of the gas engine side of the unit is the mechanism for operating the valves, which, instead of operating these by means of eccentrics, they are worked off a cam shaft.

The make and break mechanism for ignition is electrically operated from a central station. Each end of each cylinder is provided with four ignitors for the more uniform and rapid ignition of the gas.

Small Units

In the older portion of the power house are two gas engine units. Each of these drive a 500 kva. Crocker-Wheeler generator which furnish three-phase alternating current at 480 volts and 60 cycles. The engines are each two-cylinder tandem, the cylinders being 24 in. dia. by 36 in. stroke. Each engine is also direct connected to a single stage 13 in. by 14 in. air compressor.

In addition to the above units there is also another gasteam unit smaller than the large one described above. This latter unit drives a Crocker-Wheeler generator of 1,125 kva. and furnishes 3-phase energy at 480 volts and 60 cycles. This engine is in many respects similar to the large one. The two gas cylinders arranged in tandem are 24 in. diameter and have 36 in. stroke. The high pressure steam cylinder is 18 in. dia., the low pressure arranged tandem is 34 in. dia. and the stroke is 36 in., the same as that of the gas side. The speed is 120 revs. per min.

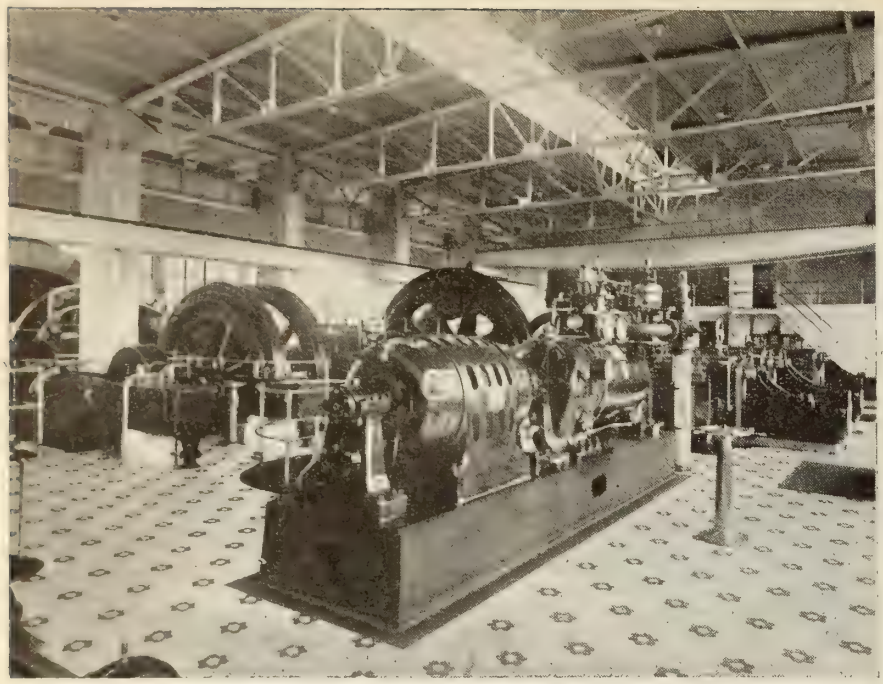
For the furnishing of compressed air to the shop there is an addition to the above gas engine driven units, a cross-compound Corliss steam-driven air compressor. This machine has 12 in. and 26 by 24 in. steam cylinders with 13 and 22 in x 24 in. compressor cylinders. The first mentioned air compressors being direct connected to an A.C. generating unit operate at constant speed of 150 r.p.m. The speed of this latter unit is controlled by an air cylinder attached to the speed limiting governor.

All of the gas-steam engines, gas engines and the air compressor were furnished by the Hooven, Owens, Rentschler Company.

The smaller gas-steam unit and the air compressor are served by a surface condenser made by the Wheeler Condenser and Engineering Company. This condenser is fitted with a 12 x 10 in. Edwards Triplex air pump.

For night duties and Sunday service a steam turbo-generator set has been installed. A Terry steam turbine is directly connected to a 150-kw., 250-volt d.c. generator, and is also connected to 3-phase motor, 3-phase 60 cycle of the synchronous type.

3,000 K.W. GENERATOR AND FLYWHEEL OF GASTEAM ENGINE.



WESTINGHOUSE-PARSONS TURBO-GENERATOR UNIT.

The above set is for auxiliary purposes while for general use a second set is installed. This unit is a Westinghouse-Parsons turbo-generator set, having a capacity of 375 k.v.a. and delivering three-phase current at 480 volts and 60 cycles. The speed of the unit is 3,600 revs. per min. A Westinghouse surface condenser of 800 sq. ft. area serves this unit.

Motor-Generator Sets

It will be noticed that two systems are in use alternating and direct current both being supplied. In order to make the distribution more flexible and to permit of the transference of load from one system to the other, motor generator sets are installed. The first of these consist of a 1,020 kva. 60 cycle synchronous motor direct connected to a 900 kva. 250 volt d.c. generator. This set is so arranged as to permit of the supplying of either a.c. or d.c. power which ever is required. Another motor-generator set is also installed, and this set performs a slightly different function. A 900 kva. synchronous motor is directly coupled to a 250 kw. 250-volt d.c. generator. It will be noticed that there is a considerable difference in the sizes of motor and generator, and while the generator is over-motored, the motor is used for power-factor correction and the d.c. generator is of service at night for auxiliary service. A power factor of 92 to 95 per cent. is maintained on the alternating current load.

Control and Ignition

A 125-volt exide storage battery is used for switch control, auxiliary lighting, and is also used during the day for ignition on the gas engines.

Electrical Features of Design

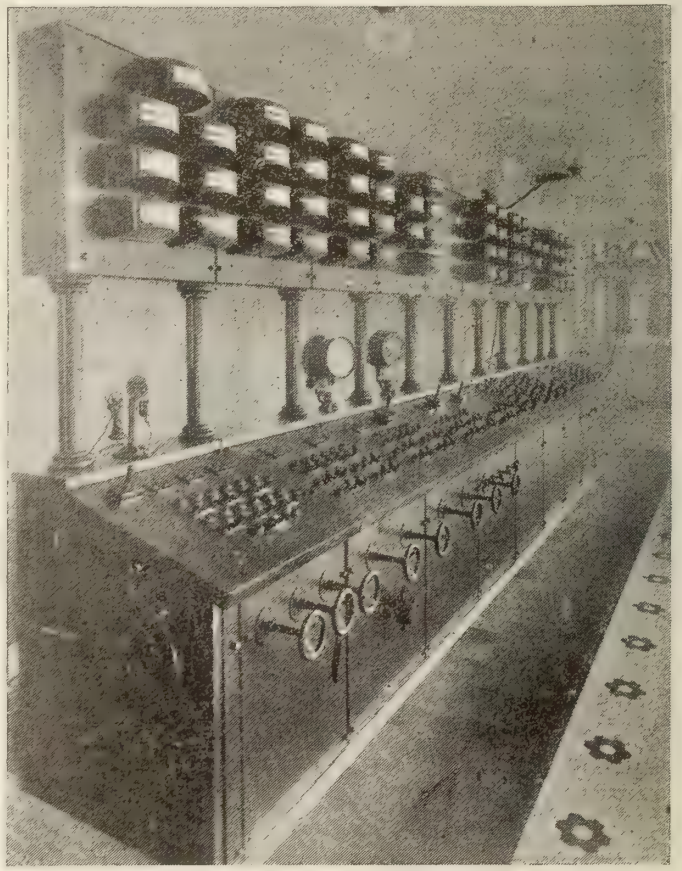
With generators of 3,000 kw. capacity and delivering current at 250 volts, the copper work and switching equipment would naturally be of some size. This is the case and leads from the main d.c. generator are of large proportions. Twelve bars of 6 by ¼ in. copper are required for the two main leads, while for the equalizer between units a six bar bus of the same size copper is used.

The generator leads are carried underneath the main floor to a wall and up and out through the roof across which they are carried to the d.c. generator switch structure. This is located on the second floor and here the main circuit-breakers for the generators are installed. The 3,000 kw. set is provided with a 15,000 amp. two-pole circuit breaker with equalizer attachment. The 250-kw. set has a 1,600 amp. breaker, 3-pole for main leads and equalizer. The 900 kw. set has a similar circuit-breaker of 5,000 amp. capacity. The feeder board from which all feeders are taken to the various departments in the shop is located immediately below the generator panels and is provided with circuit-breakers of a similar type. All these breakers are of the "I. T. E." type, made by the Cutter Company, Philadelphia.

The alternating current distribution is taken care of by an oil switch structure in a special switch room located to one side of the engine-room basement. These switches, together with the circuit-breakers, are all remote controlled from a bench board located in a gallery overlooking the engine room. This bench board is shown in one of our illustrations and has a capacity of 32 feeders in addition to the machine controls.

General Details

Throughout the entire power plant one is impressed with the effort which has been made to render it attractive to the eye. Tile floors, tile walls, and the very large glass area combine to make an engine-room at once attractive and well lighted.



BENCH-BOARD FOR CONTROL OF GENERATORS AND PLANT FEEDERS.

A Description of a New Large Gas Engine

This Engine, of 1,000 Horse Power, Embodies Some New Features of Design, Which Allow of a Considerable Saving in Space—It Has Four Cylinders on One Crank

Courtesy of "The Engineer"

THE large variety of gas engines employed a decade ago for the development of anything over small power has, within recent times, been narrowed down to two distinctive types—the slow-speed tandem horizontal design and the high-speed vertical class; but a new form of engine embodying the best features of both classes is now working in the Midlands, and its operation, so far, has been so satisfactory that it promises to become a serious competitor with its two established rivals.

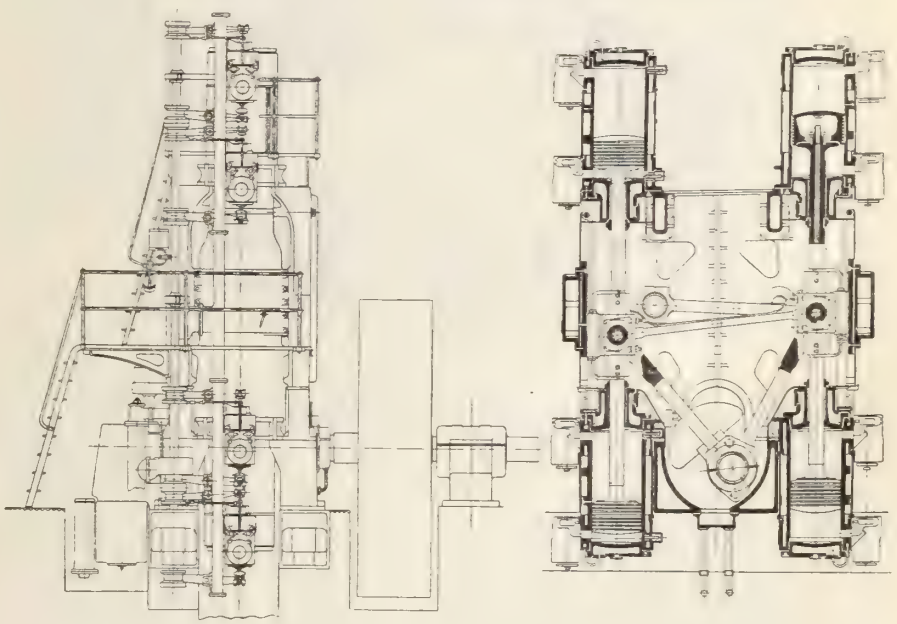
The engine in question has been the subject of a large amount of study on the part of the designer—Mr. J. H. Hamilton, of the Premier Gas Engine Company.

The consideration which chiefly guided Mr. Hamilton in designing the new engine was an appreciation of the fact that the purchasers of large gas engines, who are generally blast-furnace or steel works proprietors, have a distinct bias in favor of comparatively slow-running machinery. It may be that they are more tenacious of that love for visible reciprocating parts, than are other classes of engineers, or it may be that the rough usage of a steel works is more readily resisted by the low-speed engine; but whatever may be the cause, there is no doubt that the iron-masters of this country prefer slow-speed gas engines to the more recent high-speed vertical type. And this despite the fact that the latter engine occupies far less floor space—a very valuable characteristic in crowded ironworks. Another consideration influencing the design is the reduction of manufacturing costs to the lowest possible limit.

The result of taking all these factors into consideration is the adoption of a vertical arrangement, the four-stroke cycle, a speed of 125 revs. per minute, and a single crank for every four cylinders. The last mentioned feature is one of the greatest innovations in the engine, and helps very largely in the reduction of its cost as compared with other four-cylinder vertical engines, for, with the usual arrangement the crank shaft is the controlling factor in the price of the engine.

Referring to the sectional line drawings above, it will be seen that the cylinders are grouped in pairs. on opposite sides of the crank shaft, with a triangular connecting-rod, after the fashion of the old Musgrave steam engine, transmitting the motion of the two sets of piston rods to the single crank. The upper ends of the two branches of the connecting rod have gudgeon pins working in short transverse slides in the cross heads, while the right hand pin also takes the ends of the radius rods that transmit the side thrust of the connecting rods to anchor pins in the main frame. In this way, it will be seen the principal forces which, with the normal arrangement of crank and crosshead produce a considerable amount of friction on the slides, are taken by the linkage, and the only side thrust which is put upon the cross-heads is that produced by the friction of the gudgeon pin slides as they make the small movement (about one inch) accounted for by the circular movement of the end of the radius rod.

The arrangement possesses the advantage of reducing to a minimum the frictional losses involved in the conversion of the reciprocating motion of the piston to the rotation of the crank, and also gives a very even turning movement. The effect of the triangular connecting rod in this direction is, in fact, practically equivalent to setting the cylinder axes at an angle of 60 degs., like the familiar motor cycle engine.



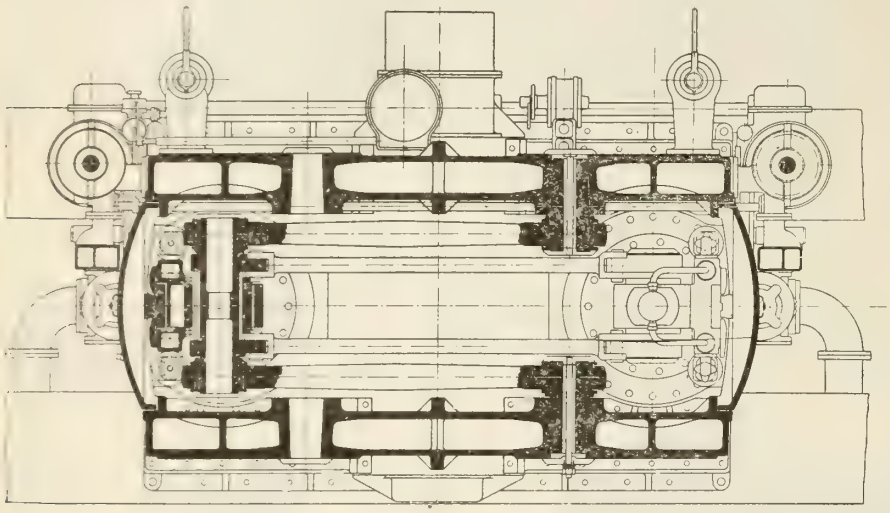
Some indication of the fact that the stresses are confined within a comparatively small part of the engine may be obtained by a visit to the upper platform. Even when the engine is working at a considerable overload, the movement at this height—some 20 ft. above the foundation—is barely perceptible, and no relative motion between the two top cylinders can be detected.

One of the peculiar detail features of the engine is the big end of the connecting-rod. It is, of course, desirable that the two lines of cylinders should be as near together as possible, not only to save space, but also to reduce the rocking stresses on the bed-plate. For this, and several other reasons, a marine type of big end is not suitable and the bearing is formed by forging claw-like extensions on each of the connecting-rods. These claws interlace much after the fashion of a man's fingers when the hands are clasped, as in prayer. The result is that the crank pin is completely embraced by the ends of the two rods, and yet either rod can be swung clear of the pin if necessary. The two parts are connected by a couple of pins, plainly shown in the cross section, which are in shear, and thus far less liable to failure than are the bolts of the usual type of big end, which are in tension. The brasses are made in four parts, with tapered exterior faces fitting into conical seatings in the big end and a gland-like arrangement is used to adjust them to the pin. There is clearance inside the crank webs for the removal of the brasses without separating the two halves of the big end.

Another detail which indicates the thoroughness with which the design of the engine has been thought out is the arrangement of the gudgeon pins. They are secured by means of cotter pins and set screws, and, as a final precaution against their working out endways, cover plates are bolted over each end.

The line drawing shows the arrangement of the links at the level of the crossheads, and the bearings of the various rods on the pins, in plan.. The radius rods are the two outside members of the group, while the pair of rods within them forms the upper side of the connecting-rod triangle. The gudgeon pins are fixed in the eyes at the ends of the two connecting rods, and have bearings for the radius rods and the cross-head slipper. The eyes of the connect-

ing-rod are provided with cotters to fix the gudgeon pin and to ensure that there is no backlash at the joints. The anchor pins of the radius rods are drilled, and copper lubricating pipes, strapped on to the sides of the rods, lead from them to the pins and slides. The oil is supplied by a double-barrel oscillating pump driven direct off the crank shaft, which sucks from a sump in the bottom of the crank case. The lubrication of the crank pin is provided for by holes drilled in the crank webs. An entirely separate system is, of course, provided to distribute the heavy oil required for lubricating the main pistons. The lubricators for this purpose have sight feeds which deliver into pump barrels, one for each supply pipe. The plungers of these pumps are lifted by a slow-moving cam and forced forward abruptly by strong springs. The lubricators are in conspicuous positions on the platform round



the engine, and a glance on the part of the attendant will assure him that any lubricator is working satisfactorily.

A feature of the engine which is no doubt largely responsible for its sweet running, is the very thorough way in which it is water-cooled. The cylinder castings are of comparatively simple form, as the valve boxes are separate castings bolted on, and the water jackets can thus be carried well round the cylinders, while the two covers are, of course, cored out for water circulation. The middle part of the jacket is formed by bolting round the cylinder cast iron "mantles," as shown above. These mantles can easily be removed when it is necessary to clean out the jackets. The pistons also are water-cooled, and in this respect the new engine possesses an advantage when compared with the high-speed type of vertical engine. The water for this purpose is carried through a telescopic joint arrangement alongside each pair of piston-rods, and is distributed from a box bolted to the side of the crosshead, which is indicated on the drawings on these pages. The exhaust valves are also fitted up for water cooling, but the makers inform us that after trying one or two types of valve they have found one with which water cooling is unnecessary. The supply of water to the valves had been cut off when we saw the engine running at Wolverhampton.

There is a separate valve box for each end of each cylinder, and each box contains three valves. The exhaust valves are below, with their spindles appearing through the bottom cover of the box, while the air and gas valves are worked by one spindle coming through the top. Between the two sets of valves there is the port communicating with the cylinder. The valves are operated by horizontal rocking levers and grooved cams on two vertical shafts running up the sides of the engine. These shafts, in turn, are driven, through bevel gearing, by a horizontal shaft running across the base of the engine and driven through a two to one skew cut reduction gearing. There is a slight tendency, on account of the effort necessary to operate the valves, for the cam shaft to rise in its bearings, and thus, although it may appear to be a rather massive shaft to stand vertically, it runs quite satisfactorily in a plain footstep bearing.

The valves are operated positively by the rocking levers, and the fact that they are properly bedded on their seats, when closed, is ensured by making the stroke of the lever too long by about 1-16 in. This extra stroke is taken up by the compression of springs arranged in the connection between the lever and spindle. This arrangement possesses a great advantage over the usual practice of employing heavy springs to perform the whole operation of closing the valves, as, in the event of the small tightening springs failing, the valve would still continue to work with, possibly, a small leakage. On the other hand, if the spring of the usual spring-closed valve breaks the valve generally stops wide open.

The supplies of gas and air are brought to the vales by two rectangular trunks. The trunk has a longitudinal diaphragm to separate the gas and air right up to the point where they mix in the valve boxes. At the lower, or inlet, end of the trunk there is a butterfly valve, connected with the governor, to regulate the amount of gas and thus proportion the mixture to the load on the engine.

Ignition is effected by duplicate make-and-break spark gaps, arranged in the valve boxes, working with current at about 10 volts. The rockers of the spark gaps are operated by tappets on the main valve cams, and a simple system of links. The effective manner in which the sparks ignite the charge may be judged from the fact that when running light we had the engine throttled down until it was going at only 44 revolutions per minute, and it still ran quite steadily.

As regards the general arrangement of the engine, the principal working parts are boxed in by the side frames, which take all the internal stresses of the engine. They are admirably adapted for this purpose, as they practically form a complete rectangular box with a cylinder at each corner, as may be seen from the section below. There are port holes, closed by sliding doors, at the sides, and above there is a good wide opening for access. It is noticeable, on looking through any of these openings when the engine is running, that there is none of the oily smoke in the crank case often associated with vertical gas engines, while the working parts are so cool that they can be handled comfortably. Inside the framing there is plenty of room, and we should imagine that fitters would have no hesitation about dropping down into it and getting to work, if necessary, immediately the engine was stopped.

Started is effected by admitting compressed air to one pair of cylinders through a valve actuated off the lay shaft. We saw the engine started with air at a pressure of 180 lb. per square inch. In about three revolutions it was up to full speed, and took up the full loda as quickly as the switchboard attendant could apply it.

The weight of the engine is distributed over the foundations by two cast box girders about 2 ft. 6 in. deep, and between them there is a small excavation for the withdrawal of the lower pistons. As the engine is erected in the Hickman power station, it has the original fly-wheel used on the test bed, supported by an outboard bearing, and a flexible coupling is used to connect it with the electric generator which it drives; but, obviously, future sets intended for electric plants would have the fly-wheel incorporated in the generator, which would then come inside the outboard bearing.

The cylinders of the engine in question are 24¾ in. in diameter. The stroke is 30 in., which, at the normal speed of 125 revolutions per minute, gives a piston speed of 625 ft. per minute. The mean eective pressure in the cylinder is 66 lb. per square inch. Working on blast-furnace gas this engine develops 900 horse-power, or 1,000 horse-power with producer gas. The overall dimensions of the engine, including a generator alongside the fly-wheel, are 18 ft. by 25 ft. b y about 20 ft. high above the floor level. A unit of approximately the same capacity, but of the double-acting tandem horizontal type, would measure 27 ft. broad by 60 ft. long. It will thus

be seen that an economy amounting to about 70 per cent. in floor space alone can be effected by adopting the new engine. This feature is brought home to the visitor to the Hickman works very forcibly. The power plant there comprises about a dozen horizontal engines, made by the Premier Company, of which the last three are of 1,000 horse-power each. The vertical engine, standing next, although it has an imposing appearance, on account of its height, is quite insignificant as regards the room it occupies.

So far the engine has run about six months in regular service, and the power plant engineer of the owners told us that it had given no trouble whatever. As soon as it is possible to provide the requisite load it is intended to run the engine continuously for four months. From the reports which we had of the performances of the other Premier engines in the station there is no reason to doubt that the new set will accomplish the task.

The Premier Company is now engaged on the designs for some larger engines of the same type, which are to have cylinders 39 in. in diameter and to develop 3,000 horse-power per four cylinders. In one preliminary design there are eight cylinders, with an electric generator arranged between the two groups of four.

SAVING IN BELT TRANSMISSION

At a foremen's meeting the other evening, one of the questions discussed was, "Why do we lose so much time in getting the full product from a machine with a new belt?"

One man asked: "Has it anything to do with the way the belt hugs the pulley?" The reply came quickly from two or three: "The trouble is the belt was not properly stretched before it was put in place."

The next man who rose, said: "All my belts jump when the belt hooks go over either the receiving or driving pulley."

Finally the manager said: "Well, let us take this up as we did the other power problems. We will have the engineering department take full charge of all the belts that are put on new in two or three rooms, for the next two weeks, and then hear their report."

When the tests were made, and the report read, the following facts were brought out:

First: All the belts, even those as narrow as 1¼ inch, showed the least trouble when stretched on the floor in the roll before being measured for the length required. This was done by securing the ends of the belt by nails at one end, the other being put in the regular clamps and drawn up a little every day before cutting to length.

Second: All the belts of whatever width that were used showed a loss in power when they were put together, either with lacing, or any other style of belt hook. Those that were cemented, with no extra thickness at the joint, showed regular transmission, no lost motion on machine or shaft, and the production very soon, after the new belt was put on the machine, came up to full product.

The tests showed such favorable results that the following rules were adopted after the points had been thoroughly discussed:

Rule 1.—All belts shall be given out only in lengths required for applying to the drive, and only after same have been subjected to a regular process of stretching, the roll being secured to the floor at one end, and the clamps applied to the other, the amount taken up being determined by tests on the exact width of the belt being kept, one inch not being reduced by the pull to three-quarters, and so forth.

Rule 2.—Any roll of belting, so stretched, that shows uneven width shall be laid to one side, and shown to the purchasing agent, to be taken up with the firm that supplied the belting.

Rule 3.—The putting on of the belts, after the order is received from the foreman of the department, shall be turned over to the belt man, who will apply the same.

Rule 4.—All the rooms will have, as standard the amount of belting used in the last twelve months, and will be credited with all the saving made by the above rules for the next two months. This to be divided at the end of each two months' period, giving 75 per cent. as the bonus to the wages in the room, and the balance as saving on the corporation overhead account.—*Belts.*

THE SMALLEST WIRELESS RECEIVER

A late British wireless invention is a portable wireless telegraph receiver. The whole apparatus—receiving coil, tuning condenser, two valve detectors, accumulator dry battery, transformers and reaction soil—goes into a box which is only fourteen inches long, thirteen inches broad, and five inches deep. The cover of the box lifts off its hinges and forms a base with a pivot on which the receiver can be rotated so as to get the strongest signals according to the direction in which the waves are coming. A compass card on the cover enables the receiver to be set in the correct position for receiving from certain stations. With this little appliance, which weighs only 20 lbs., signals can be read in Great Britain from the largest stations in France and Germany as well as in England, without any additional wires. The signals, which are read in a telephone, are clearly audible in a reasonably quiet room.

INSURANCE POLICY FOR EMPLOYEES

An insurance policy for the sum of five hundred dollars is now given entirely without cost to every employee of the American Westinghouse Electric and Manufacturing Company who has been in the service of the company for a period of six months or more. Furthermore all employees who have been in the company's service for six months or longer and who deposit a sum each pay-day in the Employees' Saving Fund equal to 2 per cent. or more of their earnings, will not only receive 4½ per cent. interest compounded semi-annually on such deposits, but, in addition, will automatically have their insurance increased to amounts up to 2,000 dollars, depending on the length of time they have been with the company. For example, a man who has been in the service of the company for at least fifteen years, and has regularly deposited in the Employees' Saving Fund 2 per cent. or more of his salary, on which he regularly receives 4½ per cent. compound interest, is presented with an insurance policy in one of the established companies for the sum of 2,000 dollars at no cost whatever to him.

STANDARDIZATION OF SHAFTING

The American Engineering Standards Committee has invited the American Society of Mechanical Engineers to act as sponsor for the standardization of shafting. The Society has already done a considerable amount of work on a set of standard diameters for transmission and machinery shafting. It is proposed that the work, which will be carried out by a sectional committee working under the rules of procedure of the A. E. S. C., shall be broadened to include the standardization of the method of determining what diameters of transmission shafting should be used for given loads, the dimensions of shafting keys and keyways, and the setting of dimensional tolerances.

STANDARDIZATION OF PIPE FLANGES AND FITTINGS

The American Society of Mechanical Engineers has been requested by the American Engineering Standards Committee to assume sponsorship in the standardization of pipe flanges and fittings. In 1914, the Society issued a report covering a schedule of pipe flanges and fittings, for diameters from 1 in. to 100 ins. for 125 lbs. pressure, and also a schedule for extra heavy pipe, covering a range from 1 in. to 48 in. diameter, and for 250 lbs. pressure. In 1918, a supplementary report was published for working pressures of 50, 800, 1,200, and 3,000 lbs.

While the work has not been active during the last year, it is now proposed that it be continued, the Society being formally recognized as sponsor, under the rules of procedure of the A. E. S. C.

Making New Line.—"The Wilt Twist Drill Company of Canada, Limited, Walkerville, Ontario, are now manufacturing a complete line of specially designed Ford reamers, catalogues of which are now ready for distribution and will be furnished on request."

The Thirty-First Convention is Now History

The Woodstock Lodge of the C.A.S.E., the Mayor and Aldermen of the City, and the Citizens at Large, All Contributed to the Success of the Occasion

By T. H. FENNER

THOSE who had the good fortune to attend the thirty-first convention of the C. A. S. E. at Woodstock, came away from that hospitable city with no doubts about its success. Pleased expressions on the faces of delegates, exhibitors and visitors were so prevalent that on the second day Old Sol could not keep away from the party any longer. He accordingly resumed the job that he had temporarily vacated and got busy drying up the picnic grounds. This was successfully completed in good time for the sporting events to be pulled off, which we will have much pleasure in describing later.

The Machinery Exhibit

The advance guard of the Exhibitors' Association were on the ground on Monday the 21st, and proceeded with the decorating of the booths, and the unpacking of their exhibits. The building allotted to them was the city market place, and it was admirably suited for the purpose. The spacious counters, chopping blocks, etc., made excellent show stands, and when the exhibitors had done their worst with the pink, blue, green, orange, and black crinkled paper, the market was transformed, and Woolworth's staff at their last gasp. Some of the decorations displayed distinct cubist leanings, and it was only through the active intervention of the Ladies Auxiliary of the G.W.V.A. that worse horrors were not perpetrated. Purple and green seemed to be the favorite, but here and there delicate clusters of pink and orange might be seen mingled with violet and yellow. However, leaving the artistic endeavors to one side, the standard of the exhibits themselves was distinctly high. The various firms sent a large and varied assortment of their products, and these were displayed, and their various points explained in minute detail by the indefatigable representatives. We understand that in some cases their trouble was rewarded by the receipt of orders which were well worth while. This is very satisfactory, but even those not fortunate enough to book orders on the spot no doubt laid the foundation for much future business. The following engineering specialty and supply houses were represented:

Mason Regulator and Engineering Co., Toronto and Montreal, showing the Reilly heater, Bundy steam traps, Mason reducing valves, steam gauges, etc. Mr. S. Balmfirth was in charge.

C. B. Turner, Toronto. Mr. Turner, looking hale and hearty in spite of his recent illness, was on hand with samples of sediment removed from feed water by his patent process, as well as high temperature fire clays, etc. There were many visitors to "Dad" Turner's corner.

Dearborn Chemical Co., represented by Mr. Hunter, had interesting literature descriptive of their treatment of boiler feed waters, and the various chemicals employed.

James Morrison Brass Manufacturing Co., Toronto, had a very complete line of their products on exhibition, while Mr. Betton was on hand to explain their leading points. All kinds of valves were exhibited and a handsome gauge board, mounted with steam, vacuum and compound gauges had a prominent place. The cross-section reducing valves and injectors came in for much attention from the visiting engineers.

The Dart Union Co. had a tastefully decorated booth, presided over by Lieut. L. Archibald, who evidently wished to be reminded of his flying days. His booth was frescoed round with miniature Zeppelins, from which depended brightly-colored darts, with the well-known union featured at the end.

The Morehead Bickle Co., Woodstock, had on exhibition a working model of their Morehead trap. This had a section of the metal cut away and replaced by a sheet of mica, through which the water could be seen mounting to the level, at which the trap dumped and cleared itself. Mr. Bickle was on hand to explain its features.

Thomas Gordon Co., Hamilton, sales agents for the Philadelphia Rubber Co., showed their various lines of packing, etc., to an interested audience.

Allen General Supplies, Toronto, had a booth from which literature dealing with their lines was distributed. These included Venturi meters, Coppus blowers and Cope's feed-water control.

The Goldie and McCulloch Co., Galt, represented by Mr. Earl Hetherington, occupied space at the entrance to the exhibition hall, where information on their high-grade engines, boilers and power plant specialties was freely available.

Darling Bros., Montreal, heating specialists, showed their radiator traps, etc., while Mr. Curzon, Montreal office, and Mr. Worthington, of the Toronto office were present to explain the principles of their equipment.

Jenkins' Valve Co., Montreal, had an exhibition of their well-known steam and water valves, of the gate and globe variety. Mr. J. S. Mock had charge of the exhibit.

France Packing Co., Philadelphia, ably represented by Mr. "Bob" Jones, showed their metallic piston and valve rod packing.

Geo. W. Cole Co., Toronto, had a couple of their steam traps on the stand, and were represented by Mr. Grant Cole and Mr. W. H. Auger.

The Valve Engineering Co., Toronto, showed their lines of packing metallic hose, etc.

C. A. Dunham Co., Ltd., Toronto, heating specialists, showed the Dunham radiator trap of the diaphragm type, and were represented by Mr. Peterkin.

The Garlock Packing Co., Galt, showed their well-known lines of engine and pump packing, pointing material, etc.

Republic Flow Meters of Canada, Ltd., had a working model of their electrically-operated flow meter erected in the hall, which was a subject of much interest.

W. R. Sexton, Toronto, showed a set of "Nonpareil" shaking and dumping grate bars, and Mr. Sexton was present in person to demonstrate the merits of these bars.

Power House was on hand to meet its many friends, and was represented by Mr. T. H. Fenner, editor, and Mr. Tressider, advertising manager.

Power, New York, was ably represented by the ever popular Jack Armor, who passed up an engagement in Montreal in order to meet his friends of the C. A. S. E.

Canadian Manufacturer was effectually displayed, and represented by Mr. Gordon C. Keith, Editor.

The Business Sessions

The business sessions of the convention were started promptly at 10.30 a.m., June 22, by the president, Mr. George Moll. Mr. Moll rounded the delegates up and got everything started on time, and carried through with alacrity. A number of questions of interest to the members were brought up, among them being a proposed amendment to the licensing laws. This would have the effect of more strictly defining the word emergency in the Graded Certificate Act, and keeping its interpretation more in line with the spirit of the Act.

Some slight changes were introduced into the preamble of the constitution of the C. A. S. E., and these will be made known to the members of the respective lodges in due course. The subject of closer affiliation with the North-Western Association of Mechanical and Electrical Engineers of Edmonton was also discussed, and it was decided to proceed along these lines.

The sessions were continued daily until the closing day, at which the officers of the Grand Lodge were chosen for the ensuing year. These are as follows:

Past President, George Moll, London.
President, R. C. Leitch, Toronto.
First Vice-President, Fred Harper, Kingston.
Secretary Treasurer, R. J. Ellis, Hamilton.
Conductor, W. Fyfe, Montreal.
Doorkeeper, R. E. Rodney, Ottawa.

John Hale, the retiring secretary-treasurer, becomes an honorary member.

On Tuesday evening a combined educational session and a smoking concert was held in the City Hall, which had been kindly lent by the Mayor and Aldermen of Woodstock for the use of the convention. The Woodstock Lodge provided the necessary smoking material, and the genial Geo. Moll filled the chair, both physically and officially.

Proceedings were opened by the reading of a paper entitled, "A Few Parallel Lines," by Mr. W. H. Auger, which dealt rather cleverly with circulating systems of various kinds.

A very able paper on "Combustion Engineering" was read by Hartley B. Gardner, of Toronto and Boston, and a copy of this will be sent to all members. The reading of the paper was followed by a short speech by Mr. A. M. Wickens, who made several apposite comments on the subject.

The serious part of the session being disposed of, Mr. Geo. Moll upheaved his six feet odd of good humor and comradeship, and called on Mr. "Bob" Jones to lead in a little community singing. Mr. Howard Fletcher proceeded to the piano and the assembled delegates responded right lustily. Following this, Mr. Jack Armor took the stage and rendered his famous monologue. Many of his stories proved just as popular to the audience as they were a year ago. "Jack's" place in the favor of the C. A. S. E. members is so secure that he could probably get an encore by reciting a section of the O. T. A.

While the mere men were thus being instructed and amused, the ladies were entertained at the moving picture theatre, so that nobody was neglected. Everyone retired to their homes and hotels feeling that the day had been well spent and looking forward eagerly to the morrow.

The Big Day

Wednesday, the day scheduled for the picnic, dawned dull and rainy, and when exhibitors and delegates met in the exhibition hall much doubt was expressed as to the chances for the picnic. The delegates went to the City Hall at 10.30 to resume their session, and the exhibitors spent the morning at the exhibition showing their specialties to interested visitors. It was felt for a time that the afternoon sports would have to be postponed, but shortly before noon the clouds cleared away and the sun came out with such vigor that before the time set for the sports the ground was dried up and in great shape.

The picnic and sports were held in the beautiful South Side Park, and the automobile owners of the town lent their cars freely to the visitors, taking them down to the park. Not only this, but a drive round the outskirts was included. Everybody turned out, and the city lent their brand new fire truck, which accommodated quite a crowd. In fact there was nothing the city could do to make things go that was not done.

The sports were under the direction of Mr. E. B. Curzon and Geo. E. Moll. Mr. Moll's dulcet voice came in splendidly on this occasion, as the announcements made by him could be heard distinctly in Brantford.

The first event was a sprint of 100 yards, won easily by Douglas Shearer, and W. H. Worthington second. The time was not given out publicly, but we heard the winner claiming it at 9 3-5. This would seem to be a pretty good gait.

The second event, a 50 yards dash, for the wives of engineers, resulted in a win for Mrs. McCalley, Mrs. Leitch being second. The result was rather surprising, neither of the ladies being of the greyhound type.

The wheelbarrow race resulted in a win for Messrs. Thompson and Worthington, the runners-up being Messrs. Cook and Sexton.

The ladies' clothes-pin race proved full of amusement to participants and spectators. The pins had to be plucked off a line by the teeth, carried to a hat and dropped in without the aid of the hands. The men holding the rope, contrived to keep the pins from being too steady, and the frenzied endeavours of the ladies to get a firm grasp with their teeth were well worth watching. Mrs. Leggodel proved the best, and Mrs. Darville came a good second.

The donkey race for men was a humdinger. The writer thought it an appropriate race for himself to enter, and therefore picked out a partner who looked as though he could bring home the bacon. At the time of entering, the fact that the rider becomes the ridden half way through, was not clear to deponent. The first half of the race, when your editor was riding was fine, but at the half-way mark his judgment in picking a steed came back on him. Said steed, one Peterkin, was rangy of limb, and about 250 pounds on the hoof, and was fine for carrying purposes, but not for being carried. Therefore it was no surprise to the team, when, in an endeavor to make a little spurt, rider and steed collapsed with a loud crash. If it had not been for that we might have won. As it was the winners proved to be Messrs. Watson and Gordon, closely followed by Fyfe and Galloway. The next time the writer goes in for a race of this kind he is going to have two partners, one to carry and the other to ride.

A soap race for married ladies was won by Mrs. G. M. Wilkinson, Mrs. M. O. Fox being second.

Peanut race for unmarried ladies was won by Miss G. DeBrool, Miss Mary Smith being second.

In the men's smoking race, Mr. Pike was first, and the versatile Mr. Worthington second.

The little boys' race was won by Fred Abbott, second being Joseph Kean.

Aquatic Events

Following the running off of the various races, a move was made to the lake side to view the rowing and paddling events. The first of these was a skiff race, there being three entries. The interest in this was somewhat diverted by the fact that each contestant chose a course of his own, which made it something like a three-ringed circus to watch. Mr. Berry caught the judge's eye, and was declared winner.

The great event was undoubtedly the canoe race. There were such glorious possibilities, though much anxiety was displayed by the spectators. This was due to the fact that the course lay around an island, and it was feared that the canoes would upset behind this island, thus robbing the spectators of part of the show. However, much to the regret of all present, no one capsized. When the start was made there were so many bumps and collisions that hopes for a general upset ran high, but these subsided as the contestants gradually cleared away and disappeared round the island. They soon came in view again and spread out over all the water available, the first crew to cross the line being James Noble and S. Shearer, closely followed by L. M. Archibald and Berry. There was considerable noise for a few minutes caused by the unsuccessful competitors explaining the various accidents that happened them. However, order was soon restored, and the victors were toasted in a foaming beaker of "near-beer."

A so-called football match between engineers and supply men wound up the day, the score in this game being 0-0. Some of the players thought different, but the referee being George Moll, nobody had the necessary nerve to argue it out.

A Great Evening

The evening's entertainment in the City Hall was presided over by Mayor A. J. Gahagan, who received quite an ovation when he rose to open the proceedings, the audience singing, "He's a Jolly Good Fellow," and giving three cheers and a tiger. Mr. Gahagan spoke briefly, saying how glad the city was to welcome the convention, and the pleasure it gave the officers and citizens of the city to entertain their visitors. Mr. Moll, in replying, gave expression to the appreciation felt by delegates and exhibitors, of the open-handed hospitality extended by the city. The convention had never before had such excellent quarters and facilities extended to them. Mr. Moll also expressed appreciation on behalf of the delegates to the officers and members of the Woodstock Lodge, who had given so much of their time to ensure the success of the convention.

The programme which followed was excellent in quality and varied in character. Although the programme declared no encores, several of the artists were obliged to respond to recalls. Notable among the numbers was the rendering of "Mother Machree," and "Darling, I Am Growing Old," by Mr. Bob Jones, whose well-manipulated tenor voice showed to great advantage. Two pretty Irish songs by Miss Edna Fowles, and Highland dances in costume by Miss Campbell, also drew encores. Mr. Earl Hethrington's tenor was well displayed and received appreciative applause. The programme wound up with a speech by

Jack Armor, which made the hit of the evening.

The prize drawing then took place following which a most enjoyable dance was held. Miss Watson's orchestra supplied the music and there were many pretty partners to choose from. This event was, to many, the crowning success of the convention.

The Last Day

Thursday, after the previous day's excitement, was calm, and strictly devoted to business. The C. A. S. E. delegates elected their Grand Lodge officers, and installed them during the afternoon. Their names are given earlier in this report. The Exhibitors Association held their meeting, and the following officers were elected for the coming year:

C. B. Turner, Toronto, president.
Grant Cole, Toronto, vice-president.
Lloyd Archibald, Toronto, treasurer.
Robert Jones, Philadelphia, assistant secretary.
Earl Hethrington, Galt, chairman entertainment committee.
A. Betton, Toronto, chairman exhibits committee.
J. Thompson, Montreal, chairman reception committee.

A vote of thanks was tendered to Mr. Bickle, of the Morehead-Bickle Co., for his kindness to the exhibitors in lending motor trucks and other services.

A vote of thanks was also passed to the entertainment committee.

The 1921 convention will be held in Ottawa. The general consensus of opinion is that wherever future conventions are held they will have to "go some" to beat Woodstock.

Following are the officers of the Woodstock Lodge, to whom is due much of the credit for the success of the convention:

J. McCalby, past president.
R. Arnup, president.
J. Precious, vice-president.
J. Dixon, recording secretary.
N. Abbott, financial secretary.
W. Jameson, treasurer.
W. Davidson, conductor.
P. R. Thuell, doorkeeper.
J. Carney, J. Cross and A. Leggo, trustees.

STOKER MANUFACTURERS ASSOCIATION MEETING

At a recent meeting of the Stoker Manufacturers' Association held at Lakewood, New Jersey, the following officers and executive committee were appointed: Sanford Riley, president; M. Alpern, vice-president; A. G. Pratt, treasurer; S. A. Armstrong and H. A. Hatton, J. G. Worker, secretary.

This committee is to meet in New York at an early date to name the standing committees of the organization for the coming year. A vote of appreciation and a round of cheers was tendered to P. A. Poppenhusen, the retiring president.

When asked for a statement after the meeting in regard to his policies for the organization during the coming year the newly elected president, R. Sanford Riley, made the following statement:

"I have always believed that the stoker business is a good one, but it has not even yet taken its proper place in the business world. I have seen it develop from a very crude business, conducted on comparatively low plane, to a large business conducted on a much higher plane. We are getting an increasingly large percentage of able men in the business which makes it good, not only for those in the business but also for our customers. After all, we can profit only as we serve, and the service possible in our business is one of the greatest in any line of business.

"We are no longer the leading propagandist in the art of conserving fuel. The Government seems to have taken over the position and all we have to do now is to live up to the demands made of us.

"Our field is being enlarged every day by economic pressure, and my hope is that we, as an association, may conduct ourselves so as to be worthy of the field."

Mr. J. G. Worker was then asked what his views concerning the Stoker Manufacturers' Association and its usefulness in the trade and to the country generally were, upon which Mr. Worker said:

"As soon as real live business men get together in any sort of a meeting, and their personal efforts are directed towards a common cause, nothing but a definite constructive program can be expected. Just such a meeting was the beginning of the Stoker Manufacturers' Association. The fact that 99 per cent. of the stoker manufacturers of the United States are members of this association is significant. The function of a modern trade association are to furnish information and service to its members that they could not very well get outside and help to educate them, their members and their customers. Associations stimulate the members to improve the quality of their product and the service that they render and the tremendous influence for the industry as a whole is exerted by those associations that maintain a high standard and refuse admittance into the association of any concern who does not come up to the association standards. Whenever any real constructive measure is adopted by the association every one interested in stokers, including manufacturers, salesmen, and customers are helped. One of the things that the associations are doing and going to do is to have every real stoker manufacturer of the United States a member of the association, and emphasize by the character of the association the fact that the association stands for honest merchandising and for putting the stoker business on the highest level of business ethics."

Gates Refractories, Ltd., of Montreal, have recently obtained some good contracts for boiler installations and special firebrick.

INTERESTING BULLETINS

The Wellman-Seaver-Morgan Company, Cleveland, Ohio, have published a very thorough and attractive line of bulletins, covering some of their varied field of activities. The booklets show some interesting installations made by this company and are highly instructive. Following are the subjects which we have so far received:

Bulletin No. 41 deals with coal and ore handling machinery. The W-S-M. unloaders, travelling bridges with grab buckets, car dumpers, car haulages, transfer cars, boat loaders, bucket handling cranes, excavating buckets and weighing lorries are shown.

In Bulletin No. 42, special cranes are illustrated, pontoon cranes for marine work, dock cranes, shipbuilding cranes, cranes for concrete handling, and also some special purpose cranes.

The other bulletins received take up in detail the following subjects: No. 43 goes into the subject of hydraulic turbines; No. 44 shows hoisting and mining machinery; No. 45, steel works equipment; No. 46, coke oven machinery; No. 47, port and terminal equipment; No. 48, rubber machinery; No. 30, W.-S.-M. charging boxes; No. 26, tire running press; No. 18, the operation of a gas producer, and No. 19, superseding No. 13, illustrates their tire applying press.

Bulletin No. 22 gives the relations between power, shaft diameter, torsional stress, and speed of any shaft, and we hope in this latter case to present the charts for our readers' benefit.

All of these bulletins are prepared in splendid style, and we have been informed that they will be sent to anyone interested.

At the conclusion of a tour of inspection of Canadian shipyards Sir James McKenzie, managing director of Vickers Ltd., of England, stated: "I am surprised at the magnitude of these yards and also at the economic layout of the plants, and I have seen the most modern machinery in these plants that exists anywhere today, and for the first time in my life I am ready to admit that there is a great future for the shipbuilding industry of Canada. I have no hesitation in saying that the acquisition of the companies owning these plants is absolutely essential, in my opinion, to the existence of the British Empire Steel Corporation. It will only be following out the same lines as have been adopted by the United States Steel Corporation and our big steel interests in England, where they have control of their shipping and shipbuilding plants."

Molybdenum Steel.—Production rights for the new Arnold high-speed steel method have been acquired by J. D. Moffat, a director of the Sir Thomas Salter Pyne Company, of Sheffield. The company in question is making preparations for placing the new steel on the market at a lower price than tungsten steel.

The Theory and Practice of Electricity

In These Articles the Theory Will be Developed Sufficiently to Enable the Practical Man to Grasp the Underlying Principles of Apparatus Under His Care, Both Direct Current and Alternating

By W. F. SUTHERLAND

IN the last section a number of the characteristics of the electric circuit were discussed, and was shown that the flow of electrical energy through a wire had certain characteristics somewhat similar to the flow of water through a pipe. It was found that a property existed somewhat similar to the pressure which causes water to flow through a pipe; it was found that the rate of flow was measured likewise and finally it was also stated that a property, inherent in the wire, existed similar in its effects to the frictional resistance which exists in a water pipe and which retards flow through it.

This lesson will be devoted to the study of these three properties, pressure, rate of flow and resistance, and it will be found that a certain relation exists between the three characteristics of the electric circuit.

The unit of electrical pressure which is in common use for measuring potential or for purposes of calculation, is the "volt," as has already been seen. Similarly, the unit of current flow is called the ampere, and that of resistance is called the ohm.

All these units are more or less based on abstract considerations in their magnitude, and the physicist can go right back to the fundamental units of length mass and time, and can express the units of electrical measurement in these. For our purposes this is decidedly an unnecessary refinement, and we will be quite safe in saying that the units of electrical measurement are to-day fixed in much the same way as those of weight or length—by Government standards.

Starting with the unit of flow we have seen, in the last lesson, that it is the rate of flow which will allow a certain definite quantity of electricity to flow in one second. To cause this flow an electrical difference of potential or pressure must be created, for all circuits have more or less resistance. To this unit of electro-motive force or potential, is given the name of "volt."

To define the volt we must take into account the resistance of the circuit and can consider it measured in terms of the unit—the ohm. The definition of the volt can now follow, and it may be defined as follows. "The volt is the unit of electrical pressure or potential difference which causes a current of one ampere to flow through a resistance of one ohm. The ohm in turn is defined in terms of the resistance of a column of mercury of a very definite length, weight and cross-section.

Also when a current flows through a circuit having a resistance of one ohm and under, a pressure of one volt, the value of the current is said to be one ampere.

When an electro-motive force of one volt causes a current of one ampere to flow through a resistance, the resistance is said to have a value of one ohm.

The law which is implied in the above statements, and in that which follows, is called Ohm's law, and it holds universally true for direct current, although it is only applicable for one particular condition when alternating current circuits are considered.

All three of the above statements are mutually dependent and in effect are merely different ways of expressing the same thing. In algebraic notation they may be more simply expressed, for if we let

E=the electro-motive force in volts;
R=the resistance in ohms;
I=the current strength in amperes;

then

$$I=\frac{E}{R} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots 1$$

$$E=IR \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots 2$$

$$\text{and } R=\frac{E}{I} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots 3$$

For the benefit of those not conversant with equations to any extent, these may be expressed as follows:

Equation 1.—The current in amperes equals the volts across the apparatus or line divided by the resistance.

Equation 2.—The volts which will cause a current of so many amperes to flow through a resistance of so many ohms, will be given by the product of the number of amperes multiplied by the number of ohms in the resistance.

Equation 3.—The resistance in a circuit which has so many amperes flowing through it can be found by dividing the voltage by the number of amperes flowing through it.

An example or two will serve to show how this law may be applied to an electric circuit of a simple kind. In Fig. 7 is shown a complete generating and transmission system in miniature. A generator is shown, transmission lines are shown and a means for utilizing the energy is also installed at the end of the line remote from the generator. In the figure, the resistance of all the separate parts is also indicated. It may here be remarked that the resistance of the generator must be figured in, since although it supplies the energy, the current must flow through it as well as the rest of the circuit.

If the generator is generating electrical energy at 110 volts pressure and we wish to obtain the number of amperes flowing through the circuit, this can be done as follows:

The total resistance is $6+5+5+7=23$ ohms, the voltage 110, and since

$I=\frac{E}{R}$, dividing 110 by 23 we obtain

4.77 amperes as the answer.

If we put an ammeter on the circuit and found 5 amperes flowing through the circuit and knew that the resistance was 23 ohms as before, it would be possible to find the voltage generated.

$E=IR$.

Multiplying the 5 amperes by the figure denoting resistance, we would obtain $5\times23=115$ volts.

Or, if the resistance were unknown but we could find the number of volts and the number of amperes, it could readily be found. Let us suppose a voltmeter registered 100 and 5 amperes were flowing through the circuit. Then since

$$R=\frac{E}{I}$$

dividing the voltage by 100, by the amperage, 5, we would obtain 20 ohms for the resistance.

In Fig. 7 and in the descriptive matter which dealt with it, a complete circuit was dealt with. It is also possible to use ohm's law when dealing with only part of a complete circuit, as shown between A and B, Fig. 8. A resistance is shown and it is desired to find the number of ohm's value it has. A voltmeter is connected in the circuit across the ends of the resistance and an ammeter is also inserted in the main current. If the generator or other source of energy is connected in the circuit, two readings will be obtained, the current strength and the voltage across the resistance. Ohm's law will give from these two quantities the value of

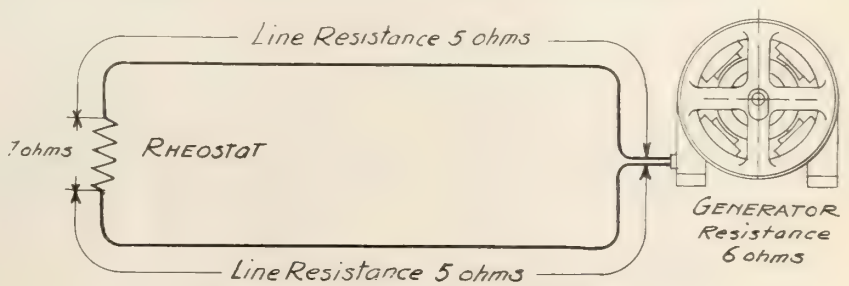


FIG. 7.—EXAMPLES OF A SIMPLE CIRCUIT.

the resistance directly, for $R = \frac{E}{I}$. For instance, should we find that the voltmeter indicated 10 volts, while the amperes were 5, the resistance would have a value of $10 \div 5 = 2$ ohms.

The connection shown in Fig. 8 gives a very convenient method of finding the value of resistances, and is very useful. It should be remarked, however, that the reading of the ammeter in the connection shown includes the very small current taken by the voltmeter, and this must be allowed for if fairly accurate results are desired.

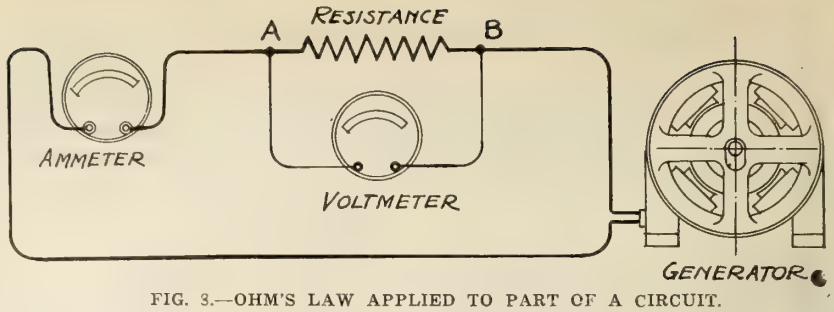

FIG. 3.—OHM'S LAW APPLIED TO PART OF A CIRCUIT.

Various Types of Electrical Circuits.

The complete path through which an electric current flows is called a circuit; this circuit may be a closed one, in which case the current has a complete path and flows with only whatever resistance may be present to impede its flow. Or a switch may be opened, and since a break has been created in the circuit no current will flow, in this case an open circuit is said to exist. Short circuit is a term given to an accidental connection between two parts of a circuit which cuts out a large amount of the total resistance and in consequence allows a large current to flow, frequently with disastrous effects.

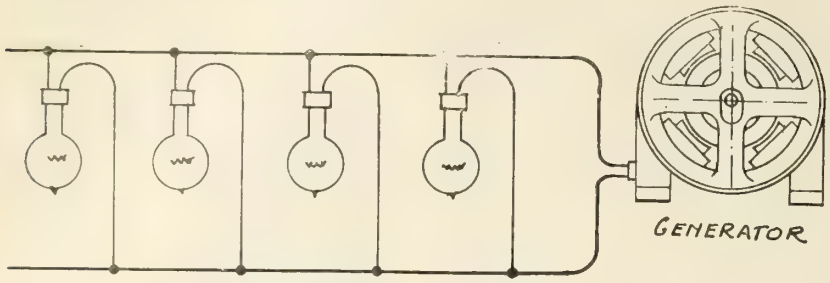

FIG 9.—EXAMPLE OF A SERIES CIRCUIT.

A circuit is said to be grounded when one of the conductors is connected to the ground in some manner, either by accident or design. Accidental grounds on machines or lines give rise to much trouble at times, when conditions are right for the flow of current through them instead of in the proper channels.

It is possible to dispense with one leg ground connection at each end of the line. When this is done the earth acts as one side of the line. The early telegraph and telephone systems were almost invariably built this way but complete metallic circuits are more in favor at the present time.

The rails are used in street railway work for the return conductor, and if well bonded together serve admirably for the purpose. If the bonding is poor however, serious trouble is likely to arise through stray currents leaving the rails and using water mains, etc., as conductors. In this case where the current leaves the mains, electrolysis occurs and the metal is rapidly eaten away.

Electrical circuits are of bewildering complexity at times, and to one unaccustomed to their tracing out, offer many difficulties. While this is true, the majority of circuits can be resolved into two kinds, or a combination of them, and a familiarity with these types enables one to readily understand the computations and design of circuits in general.

Figure 9 shows a generator feeding a load consisting of five lamps. By starting at the generator and following the connections through, it will be seen that the current must flow through first one lamp and then the next and so on, finally leaving the last one in the series and returning to the generator. A circuit of this type is called a series circuit since the current must flow through all the lamps in series. If we suppose the lamps to each have a resistance of 50 ohms, by multiplying this value by the number of lamps we would arrive at a value of 250 ohms for the total resistance. If now the generator was delivering current at a pressure of 500 volts, the current would be $500 \div 250 = 2$ amperes. Series circuits were quite frequent in the days of the old arc lamp, and while the current carried was very moderate, the voltage generated by the dynamo was often quite high, several thousand volts. A similar type of circuit is also in use to-day in smaller towns for tungsten lights. Here a current of say five amperes is used, and the voltage is automatically regulated to keep this value constant. Circuits of this type are often called constant current circuits.

Fig. 10 shows another arrangement of the generator and the five lamps. In this case the current leaving the generator splits into five parts, and each lamp takes a portion of it. If we had five amperes at the generator, and only one would flow through each lamp.

While in the case of figure 9 the voltage would have to be varied to keep the current strength constant for different numbers of lamps, in the case of Fig. 10 this no longer holds good. Let us suppose we have the five lamps in circuit and each one of them requires one ampere, the total current supplied by the generator would be $1 \times 5 = 5$ amperes. If one of the lamps were cut out, then only four amperes would have to be supplied, and at the same, or nearly the same voltage. This type of circuit is called the multiple circuit.

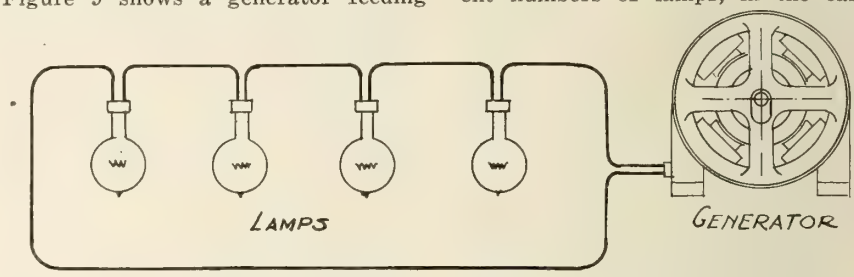

FIG 10.—EXAMPLE OF A MULTIPLE CIRCUIT.

A combination of the two types of circuits is possible, and is shown in Fig. 11. Four lamps and one motor are shown connected to the generator. Two lamps are connected together and their outside terminals are connected to the lines while the motor is connected in by itself on the lines. If the voltage generated is 220, it will be seen that while each group of two lamps has 220 volts

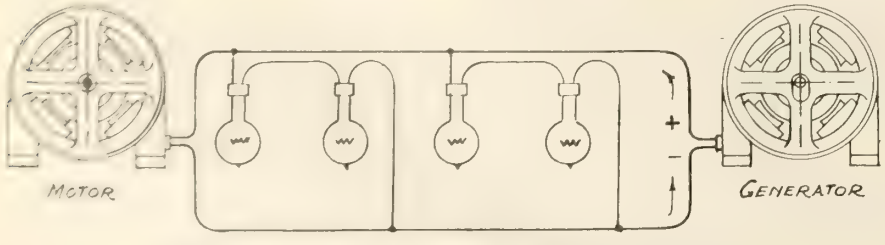

FIG. 11.—EXAMPLE OF A SERIES MULTIPLE CIRCUIT.

across the outside leads, each lamp will have only half of this, or 110 volts. The motor will have the full voltage or 220 volts, across its terminals. Each group of two lamps forms a series circuit, while the two groups of lamps and the motor form a multiple circuit. The combination is called a multiple-series or series-multiple circuit. The multiple circuit is also called the parallel circuit, and the two terms are used interchangeably, as are series-parallel and series-multiple.

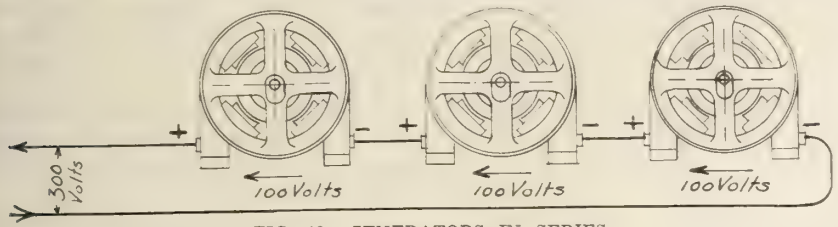

FIG. 12.—GENERATORS IN SERIES.

The Grouping of E. M. F.'s

The above examples have only dealt with the arrangement of lamps or other current consuming devices in series or parallel. It is possible, and is being done every day, to group generators or other means of creating electrical energy in a similar way. Fig. 12 shows three generators connected in series, and before discussing the results obtained from this grouping it may be well to take up the question of current flow. From various actions of the electric current on liquids through which it flows, and through its relation to electro-magnetism, it is surmised that the current flows in one direction or the other, and, while it is doubtful as to which direction it really takes it is assumed that the carbon pole of a battery is positive and the current flows from it and in at the zinc again. Polarity is indicated frequently by plus and minus signs, and the sign (+) means positive, while (—) is negative. The three generators shown in Fig. 12 all tend to make the current flow the same way as shown by the arrows underneath them. Each one of them is supposed to be generating current at 100 volts, and the combined result of their action is the build-

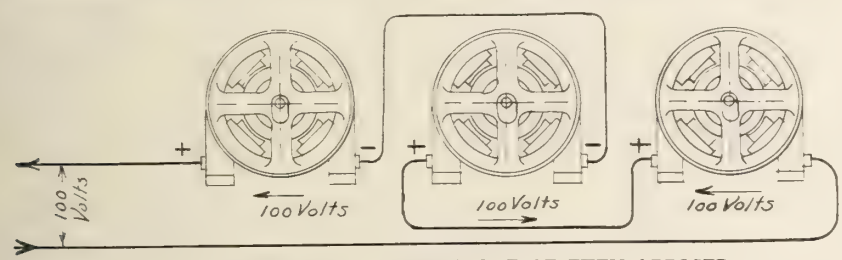

FIG. 13.—GENERATORS IN SERIES, ONE OF THEM OPPOSED.

to the remaining one, 100+100—100=100 =300 volts.

Fig. 13 shows the same arrangement except in that one of the generators has been reversed, and is now opposing the other two. In this case two of the generators neutralize each other and the voltage generated is only that due to the remaining one, or 100+100—100 =100.

In the case of a series connection such as above, it should be noted that the current strength does not change by the addition of more generators, but the voltage does.

A form of series connection which is of very common occurrence is shown in Fig. 14. A generator charging a storage battery has its positive terminal connected to the positive terminal of the battery, for while the battery is discharging current flows out of the positive terminal, when on charge conditions are just reversed and current is lead in at the same point.

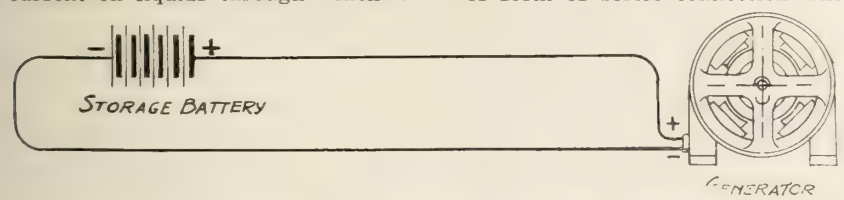

FIG. 14.—ELEMENTARY BATTERY CHARGING DIAGRAM.

Generators can be, and are quite frequently, arranged in multiple. Fig. 15 shows a connection of this type. If each of the two generators is furnishing 25 amperes at 110 volts, then the line current will be 25+25=50 amperes, while the voltage remains the same, namely 110 volts. If one of the generators had its leads reversed it would act as a motor and would supply no energy whatever.

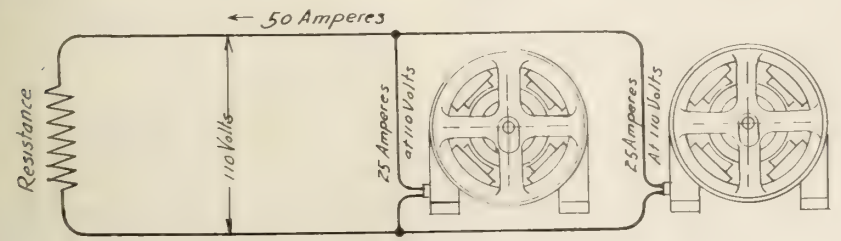

FIG 15.—GENERATORS IN MULTIPLE.

HANDY RULES FOR BELTING

Rules for finding length of crossed belts:—First, find the length of straight belt. Square each the diameter of the large pulley and distance between centres. Add together and extract equare root of sum. Subtract from this the distance between centres. Multiply the remainder by two and add to length of straight belt as previously found. The result will be the length of crossed belt.

As a belt depends entirely on its power of adhesion to the pulleys to perform its function, see to it that its power of adhesion is maintained at the maximum by not overloading, and by the consistent use of suitable belt dressing, sparingly but regularly applied. Do not allow the dressing to clog on the pulleys. As belt slip is such an insidious danger—it makes no noise—and may be going on unsuspected until irretrievable damage has been done to the belt. Begin the application of belt dressing immediately the belt is put into use.

Rules for Finding Length.

When it is not convenient to measure with the tape line the length required, the following rule will be found of service: Add the diameter of two pulleys together, divide the result by two, and multiply the quotient by 3 1-7; add the product to twice the distance between centres of the shaft and you have the length required, substantially. If one pulley is considerably larger than the other, a little extra allowance should be made, because the distance from the centre of the top of one to the centre of the top of the other is a little greater than the exact distance between the centres of the shafts.

To ascertain the number of feet in a roll of belting: Add diameter of roll in Multiply the result by the number of inches to diameter of hole in centre. coils in roll, and then by 132; the three left-hand figures being the number of feet in roll.—*Belts.*

According to Wireless World there are three wireless direction-finding stations being erected at the mouth of the Mississippi River for the purpose of directing ships to New Orleans. Eight stations of this nature are also in course of construction along the Pacific Coast from San Diego to Alaska. One station, that on the Farralone Islands, is nearly completed. The sites of the other seven are at Pt. Reyes, Bird Island, Pt. Montara, Pt. Hueneme, Avalon, Pt. Firmin, and Imperial Beach.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

WE dealt in our last article with the square root, and now will proceed with the more complicated and tedious process of finding the cube root. We would again take the opportunity of recommending readers to familiarize themselves with the use of tables for this work. It is a good thing to know how to extract cube root in the ordinary way, but no busy man has got the time to go through its labored processes. The use of tables also reduces the risk of error, especially in quantities involving the roots of decimal numbers.

In extracting the cube root, the number is divided into periods of three figures each, instead of two, as in square root, beginning at the unit figure, and going to the left. The figures would be pointed off thus:—

1231456

The first step is to find a number whose cube is smaller than the first period, and this number will go in the quotient as the first figure of the root to be found. The cube of this figure is then subtracted from the first, or left-hand period, of the number, and the remainder set down. The next period is then brought down in line with the remainder, and this forms the next dividend.

The procedure so far would be as follows. Suppose we have to find the cube root of 15625. Point off into periods:

151625

Then find a number whose cube is less than 15. The cube of 3 is $3\times3\times3=27$, which is too high. The cube of 2 is $2\times2\times2=8$, which will do, as it is less than 15. Then we have

```
151625(2
  8
  --
 7625
```

The next thing is to find a divisor for 7625. To obtain this the first figure of the quotient is squared, and then multiplied by 300. This is the trial divisor. The quotient is put down after the first figure of the root. To complete the divisor, the two figures in the root are multiplied together, and the product multiplied by 30 and added to the trial divisor. The second figure of the root is squared, and also added to the trial divisor.

The sum of these operations must be multiplied by the second figure of the quotient, and the product subtracted from the remainder. If the product is greater than the remainder, the second figure of the quotient must be reduced by one, and the trial divisor altered accordingly. Let us apply these rules to the example we have:

```
151625(26
  8
  --
 7625
2×2×300=1200
2×6×30 = 360
  6×6  =  36
       ----
       1596
```

Here we have taken 6 as the second figure of the root, and used it in the operation of finding a trial divisor. The sum of the various factors of the divisor is 1596, and a glance shows that when this is multiplied by 6 the product will be greater than the remainder. We must therefore reduce the second figure of the root by 1, and try again:

```
15625(25
  8
  --
 7625
 7625
 ----
2×2×300=1200
2×5×30 = 300
  5×5  =  25
       ----
       1525
```

This divides out exactly, and the cube root is 25.

The rule as worked out above can be stated briefly as follows:

Divide the number whose root is to be found into periods of three figures each, starting from the unit figure. Find a number whose cube is less than the first period and this figure will be the first figure of the quotient, or root. Subtract its cube from the first period, and bring down the second period, which, with the remainder, forms the next dividend. To find the second divisor square the first figure of the quotient, and multiply it by 300. The product forms the initial trial divisor. The quotient of this trial divisor must be set down after the first figure of the quotient, forming the second figure of the root. To the initial trial divisor add 30 times the product of the first and second figures of the quotient, and to these add the square of the second figure of the quotient. The sum will be the final trial divisor, and is multiplied by the second figure of the quotient, and the product subtracted from the remainder. If the product is too large to subtract from the remainder, reduce the second figure of the root or quotient by 1, and correct the factors of the trial divisor accordingly.

It will be readily appreciated that unless one is using these rules very frequently, they cannot be retained by the ordinary memory. It can also be seen that there are lots of opportunities for error, in the various calculations to be made. It is a notable fact that it is very rarely one finds a designer or mathematician who can find cube root by the ordinary rules. They invariably use tables or logarithms.

We will give a few more examples of cube root, to familiarize the reader with the process, and will then leave it with no regrets.

To find the cube root of 764,839,412, we divide off into periods, and find the first figure of the quotient, which will be 9:

```
                                764,839,412(914.4
                                729
                                ---
  9×9×300=24300                 35839
  9×1×30 =  270
    1×1  =    1
           -----
           24571                24571
                                -----
 91×91×300=2484300              11268412
 91×4 ×30 =10920
    4×4   =   16
           -------
           2495236              9980944
                                -------
914×914×300=250618800           1287468000
914×4 ×30 =  109680
    4×4   =      16
           ---------
           250728496            1002913984
                                ----------
                                284554316
```

We could safely say that the cube root is 914.5. If this is multiplied out, it will be found its cube is not quite in agreement with the number, but the discrepancy can be reduced by taking further places of decimals.

To find the cube root of a decimal number, proceed the same way. Suppose we want the cube root of .5. In order to have the necessary three figures add two ciphers to the .5, making it .500. Then the first figure of the root will be .7. Thus:

```
                                .500(.7937
                                343
                                ---
  7×7×300=14700                 157000
  9×7×30 =  1890
    9×9  =    81
           -----
           16671                150039
                                ------
 79×79×300=1842300              6961000
 79×3 ×30 =   7110
    3 × 3 =      9
           -------
           1849419              5548257
                                -------
793×793×300=188654700           1412743000
```

The cube root of .5 is therefore .7937. Let us multiply this out to see how near it comes:

.7937
.7937
55559
23811
71433
55559
62995969
.7937
440971783
188987907
566963721
440971783
.499999005953

We see it is practically correct.

If we want the cube root of .005 we find the nearest cube to 5 first, as we have three figures after the decimal point. The work would be then as below:

.005(1709
1

1×1 ×300= 300 4000
7× 1×30 = 210
7× 7 = 49
559 3913

17×17 ×300= 86700 87000000
170×170×300=8670000
170×9 ×30 = 45900
9×9×300=24300 35839
8715981 78743829
.8256171

The cube root is .1709. Proving this by multiplying out we get:

.1709
.1709
15381
11963
1709
.02920681
.1709
26286129
20444767
2920681
.004991443829

which is almost exact.

It will be noted that there is a cipher in the root at the third figure. This occurs on account of the trial divisor, 86700 being too large to divide into the remainder. When this happens in any problem, add a cipher to the root and bring down three more figures in the remainder, and proceed as before.

The cube root of a fraction is found by taking the cube root of the numerative and denominator separately. Thus would be written thus:

the cube root of $\frac{125}{512}$ would be $\frac{5}{8}$ and would be thus:

$$\sqrt[3]{\frac{125}{512}} = \frac{5}{8}$$

If the fourth root of a number is required, the square root of the square root is taken. If the 6th root is required the cube root of the square root, or the square root of the cube root, is taken. or any higher roots or powers it is advisable to use tables.

The writer thinks that the preliminary ground has been covered fairly well, but if there is any point not clear to a reader, he will be glad to explain it in more detail. We will now be able to take up in the next articles definite problems relating to the requirements of the various certificates.

A CORRECTION

In the issue of June 5th, in the article on Instructions for Graded Certificates there is an error in the solution of one example. This is in the solution of the statement.

$$\frac{\frac{7}{16} \div \frac{3}{8} \div \frac{9}{27}}{\frac{5}{32} \times \frac{7}{8} + \frac{1}{2}} \div \frac{3}{4}$$

In solving the terms of the numerator of the compound fraction for the new numerator the two first turns were added before the division was performed. This is wrong as the division is merely multiplication with the terms reversed, and the two turns connected with the division sign should be simplified first.

This would then be solved as follows:

$$\frac{7}{16} + \frac{3}{8} \times \frac{27}{9} = \frac{7}{16} + \frac{81}{72} = \frac{7}{16} + \frac{9}{8} = \frac{7+18}{16} = \frac{25}{16}$$

which makes the sum

$$\frac{\frac{25}{16}}{\frac{163}{256}} \div \frac{3}{4}$$

or $\frac{25}{16} \times \frac{256}{163} \times \frac{4}{3} = \frac{111}{489}$, which is the corrected result.

In the statement that terms connected by a multiplication sign must be simplified before others, division is included, as to divide we transpose the numerator and denominator and multiply.

Coming From Germany.—According to an Ottawa despatch the articles being imported from Germany into Canada at the present time are chiefly metal, for use inclusively in mining or metallurgical operations, machinery composed wholly or in part of iron or steel, and iron or steel integral parts thereof, musical instruments and precious stones, while the importation from Austria is practically confined to electric insulators. This information was given in answer to a question by Fernand Rinfret (St. James, Montreal), in the House of Commons.

HYDRO-ELECTRIC ENTERPRISE

One of the largest electrical manufacturing groups in Great Britain has made efficient preparations for undertaking complete contracts for Hydro-Electric enterprises. The business of a prominent firm of water-power engineers and contractors has been acquired in order to provide facilities for making the largest sizes of water turbines, while the resources of the group are available for the electric generators, the construction work, the transmission of power, and all the other sections of Hydro-Electric work in any part of the world. Valuable patents have been acquired in connection with this development. A French company associated with the group is undertaking the construction of water turbines with a total output of 300,000 kilowatts, two hundred electrical locomotives, and other electrical machinery required in an important scheme of railway electrification.

ARMOR PLATE SCRAP AT SANDY HOOK

The Oxweld Acetylene Company, of Newark and Chicago, which was recently awarded the Government contract for cutting 4,000 tons of armor plate scrap to charging box size at Sandy Hook, now has a crew of oxy-acetylene cutter on the job. The plates, 3 in. thick by about 9 ft. by 13 ft., weigh between seven and eight tons each, and are being cut into sections 13 in. by 25 in., each weighing around 300 pounds. The weights vary somewhat owing to the necessity for cutting through the shell holes, each plate having been punctured six times by heavy artillery shells for which they were made the targets in the big gun tests conducted at Sandy Hook during the war.

This is one of the largest jobs of the kind that has ever been undertaken and several weeks will be necessary to complete the work.

New Cockshutt Warehouse.— The Cockshutt Plow Co., Ltd., who for the past four years have had their offices over the C. N. R. Telegraph office in Edmonton, are erecting a two-story brick building with a full concrete basement on 9909,102 A. on Rice street, opposite the city market square. The building will be fifty feet wide and eighty-five fet long. The main floor will be used as a display room, while the second floor will be used entirely for offices, from which all of the company's work for central and northern Alberta will be directed. Manager Fred Pickles says that business in the machine line this year is better than ever, and that the prospects for the future are better than at any time during the five years that the company have had their offices located here. With a display room in the centre of the city he expects that they will be able to more efficiently handle the local trade.

Some Points on the Theory of Combustion

A Paper Read Before the 31st Convention of the Canadian Association of Stationary Engineers—With Special Notes on the Selection of Suitable Mechanical Stokers.

By H. B. GARDNER

THE present practice in boiler-room operation has been virtually forced upon the engineer, this being largely due to the advance in coal costs and other operating costs. The increase in operating economies has stimulated further effort to effect still more favorable conditions. New coal-burning plants (exclusive of those burning prepared coal) are being erected, which will yield an overall boiler efficiency of from 75 to 83 per cent. The majority of the older plants, however, are not enjoying such economy. Nevertheless, except where a plant is economically obsolete an operating efficiency of less than 75 per cent is unnecessary. Adjustments may be made, improved attachments applied, and inteligent supervision and care required. Since the obtaining of heat energy at high potential is the first requisite for boiler operation, it is apparent that the success of the plant is contingent upon the economy realized in this process. It is therefore my intention to mention combustion conditions, possibilities, achievements, and recommendations, and to submit them to you for confirmation or question. I shall not touch upon effects which are not direct functions of the burning of coal or the manipulation of the resultant products.

The losses that may result from the burning of coal under a boiler are (1) that due to combustible in the ash; (2) that due to incomplete combustion; (3) that due to excess air; (4) the stock loss; (5) that due to the deposit of soot and clinker on boiler tubes, and (6) radiation from the grate and settings.

The heat lost due to unburned coal or carbon, a loss sometimes approaching 10 per cent. of the total heat value of the coal-fired, is dependent largely upon the mechanical design of the stoker or grate and the condition of the coal, though with hand-fired furnace the care in firing is a determining factor. Since a great deal of the sifting occurs very shortly after the coal is fired it has been found that in many cases a decrease in this loss of from 2 to 5 per cent. has been obtained by a preliminary moistening of the coal. Within the limits of 0 and 5 per cent. an increase of 2 per cent. of moisture on or in coal increases the stack loss by only 1 per cent. A decrease in absorption efficiency due to the reduction of furnace temperature when additional moisture is present must also be taken into account. The decrease in sifting loss, nevertheless, usually overbalances the additional losses incurred from moisture content. It is also found that by increasing the thickness of the fuel bed other conditions permitting, a reduction in sifting will result. This loss is a source of aggravation and annoyance to the boiler engineer, and I sincerely hope that a grate, and more especially an automatic stoker, may be designed which will practically eliminate it and yet preserve the advantages now enjoyed.

Loss, due to incomplete combustion, is usually of small import when considering the combustion of the ordinary coals, for practice recognizes that within limits the elimination of CO is to be preferred to the sacrifice of excess air. When the furnace is in good operation—that is with 10 per cent. or more CO_2—for each per cent. of CO in the flue gas a loss of 6 per cent. of the heating value of the combustible will be suffered. For a decrease of 1 per cent. in CO_2 in the flue gas (under this same operation) approximately 1½ to 2 per cent. of the fuel value will be lost. Engineers, therefore, prefer comparatively low CO_2 to the presence CO. As I shall later mention the practice of reducing CO_2 to prevent CO is for the most part not necessary.

Of the combustion of hydrocarbons in coal very little is understood. Most gas sampling apparatus does not separate them from the nitrogen, for until recently the effects of their presence was considered negligible. Investigations are now being made with a view to obtaining definite data as to their relative importance. Their effect is, nevertheless, small, though perhaps not negligible, since the unconsumed hydrocarbons should be small in quantity, and, moreover, as their ignition temperature ranges from 900 to 1,200 degrees Fahr., far below ordinary furnace temperatures, they should be completely burned unless there is excessive stratification of the gasses.

Many Boilers Set Too Low

Neglecting the effect of sulphur, the maximum CO_2 that can be obtained from the combustion of coal with air, may be computed from the expression

$$M = \frac{21}{1 + 2.38} \cdot \frac{(H - \frac{1}{8}O)}{C}$$

where H, C, and O, represent respectively percentages of hydrogen, carbon and oxygen in the coal, as determined from the ultimate analysis. A small percentage of CO_2 represents excess air. It has been found in many plants that complete combustion could not be attained without an unreasonable amount of excess air. This trouble may usually be attributable to a restricted combustion chamber; either a bridge wall too far forward or a boiler set too low. The general tendency is to raise the boiler, and where this has been done a marked improvement has been noted. Some water tube boilers have been raised to 12 feet above the grates. It is reasonable that with the overloads carried in modern plants the combustion space should be bigged than that which was designed for the rating of the boiler, for the older installations were made with very little, if any, allowance for overload. The more excess air, the lower is the furnace temperature and the greater is the loss of heat due to the escapement through the stack. When the CO_2 is less than 10 pe rcent. at ordinary stack temperatures, the stack loss increases rapidly. At 6 per cent. CO_2 with a stack temperature of 500 degs. Fahr. this loss is approximately 30 per cent. At 8 per cent. CO_2 it is 23 per cent.; at 15 per cent. CO_2 it is 12 per cent. These figures clearly show the necessity of obtaining as high CO_2 as possible.

How to Test Effect of Soot and Clinkers

The effect of the presence of soot and clinkers on boilers tubes is apparent. A good test for ascertaining the extent of this effect is to take the flue gas temperature before and directly after cleaning the boiler tubes. If the inside scale of the tubes is negligible a marked reduction, sometimes 50 deg. Fahr., is noted. Scrapers for the lower tubes, and soot blowers throughout should be applied to every boiler. The difference between the flue gas temperature and the steam atmosphere depends on the condition of the boiler tubes, the velocity of the gases around them, and the location and arrangement of the baffles. The stack loss is, therefore, a function of the boiler with the exception that the velocity of the gases depends upon the amount of excess air required for combustion. The maximum boiler efficiency occurs at comparatively light loads, whereas the maximum combustion efficiency is obtained with most stokers at about 125 to 175 per cent. rating. As the variation in the boiler efficiency is slight between rating and 100 per cent. overload, the maximum overall efficiency is ordinarily reached between 125 and 175 per cent. rating. When, with increase in load, the stock loss increases more rapidly than does the gain from higher combustion temperature the efficiency falls off. Incidentally, inclined baffles are found to reduce stack temperature and thus increase the boiler efficiency.

Radiation losses, which amount to from 1 to 5 per cent. in ordinary settings, are dependent upon the lagging. Leaving a dead air space in the wall has been tried with some satisfaction, though a live air space has proved much more beneficial. By passing combustion air through those portions of the

side and bridge walls which are in contact with or directly above the fuel bed, much of this radiant heat is reclaimed. If this air, moreover, is admitted into and directly above the fuel bed through openings in the wall a much greater advantage still is to be obtained. The high cost of clinkers on furnace walls is well recognized; its deteriorating action on the walls, its clogging effect on the fire, and its assumption of grate area which could otherwise be utilized are some of its main undesired results. By passing air through the brickwork on the side walls a cooling of the brick results, and an adhering surface for the clinker is thereby eliminated. A CO_2 increase of 2 per cent. has many times resulted from the better air distribution possible with the absence of side wall clinkers. A decrease in side wall radiation is also observed.

As these losses are largely dependent upon the type of grate or stoker employed it might be well to give a brief discussion on the stoker situation. It may be said that stokers designed for the work expected of them, installed with intelligence, properly handled with reasonable attention and consideration are admitted to be a great saving device. It is unfortunate that a stoker cannot be economically designed for the conditions existant in a specific plant. Although a number of different types of stokers are available there are few cases in which complete satisfaction is found. Great care is therefore necessary in the selection of a stoker, for it is preferable to have a hand-fired grate to a misplaced stoker. Such a stoker is a detriment to the pant. Many such examples are, unfortunately, existent. A slight discussion of the advisable choice of stoker for prevalent coals and definite service is therefore warranted.

Data on Canadian Coals

Canada has the second highest coal reserve of the countries of the world, this reserve totalling aproximately 1,270,000 millions of tons, consisting of 2,000 million tons of anthracite, 284,000 million tons of bituminous, and 984,000 million tons of sub-bituminous, brown coal, and lignites. This shows that the majority of the domestic coal is of the coking and high ash varieties. Professor Parr, of the University of Illinois, has specified the distinction between coking and non-coking coals. He states that if the heavier hydrocarbons (tar products) flow at a temperature below which they volatilize, the coal is a coking coal; if they volatilize first, the coal is non-coking. Most Canadian coals come under the class of coking coals. The ash content of Canadian coals varies from as low as 3.8 per cent. in the case of a coal of 16.9 per cent. moisture and 38.6 per cent. other volatile matter, to 34.2 per cent. ash with a coal having 13.4 per cent. moisture, 22.6 per cent. other volatile matter, and only 29.8 per cent. fixed carbon. The coal of highest heat value in the Dominion (14,500 B.T.U. per pound) which is found in the Crows Nest seam in British Columbia has 1.65 per cent. moisture, 6.49 per cent. ash 23.68 per cent. volatile, and 67.70 per cent. fixed carbon. This is, of course, a very good fuel. Until recently it has been common practice to import coal, mostly from the United States, it being possible to obtain the coals desired. The likelihood of a continuance of such conditions is somewhat meagre. It will, therefore, be necessary to utiize the Canadian coals and equipment should be designed especially for their consumption.

The coals which have been used in the East are mainly the semi-bituminous and bituminous coals from West Virginia, Pennsylvania and Maryland. This coal can be successfully burned in the overfeed, inclined underfeed, and some types of single retort underfeed stokers. The ordinary chain grate does not apply with this coal on account of the coking and consequent binding of the fuel bed. Some chain grate stokers have coking plates and pushers which are intended to agitate the fuel after it cokes, and in some instances such installations have proved generally satisfactory. Because of the usual thin bed carried by such stokers, however, many holes are often left between coke lumps, and this causes an excessive air stratification through the combustion chamber.

Use of Stokers Efficiently

For most industrial service when high overloads are not expected to occur, an overfeed inclined grate is very often economical. The chief advantages in such cases are in the saving of auxiliary steam and in the decrease in sifting, this latter condition being due to the fact that very little coal reaches a grate bar or tuyere before coking has occurred. Where, however, great flexibility and overloads of more than 100 per cent. are to be expected, the multiple retort inclined grate underfeed stoker is far more advantageous. The efficiency of this type of stoker will also drop off rather rapidly at high overloads, but since such overloads are usually of short duration, the saving in overhead of additional units predominates. The majority of central stations operate with this type. The sifting in the inclined underfeed stokers has been somewhat excessive, but these stokers are, nevertheless, the general favorite.

The chain grate finds its greatest application in the burning of lignites and such sub-bituminous coals. This is not due, however, to the general satisfaction of this type for such coals, but rather to the lack of any suitable design. The lignite coals present quite a distinct problem for furnace and stoker design. Their high volatile content causes a long flame which requires a long combustion chamber and at the same time necessitates a chamber which is able to offer good radiation to preserve satisfactory combustion. Attempts have been made to use a distinct coking chamber and separate gas burning chamber. I consider this method to be along the right line, though a great deal of soot has resulted with such installations, due to premature cooling of the gases. This could be relieved by a small secondary fire burning anthracite or a good grade of semi-bituminous coal in the gas burning chamber. Lignites could in this way be burned in an approximate ratio of 5 to 1 of the anthracite. The application would, of course, depend upon factors such as space available, excess equipment, and furnace construction costs. I have never heard of a plant utilizing this idea, but believe it feasible.

In connection with the installation of any stoker, the various costs incurred should be borne in mind. These costs may be classified as follows:

1. Purchase cost of equipment.
2. Installation cost.
3. Maintenance cost.
4. Cost of shut-downs.
5. Cost of labor.
6. Losses in the equipment.

It is the sum of these costs which should present a minimum in order that a particular stoker be chosen. The small points of any stoker in which trouble is found may usually be adjusted after familiarity with the operation has been acquired, but the main points of operation should be very carefully analysed, and if knowledge of operation in existing installations is not at hand, engineering advice should be obtained. Too many plants stand to-day as the so-called "horrible examples" of attempts at progressiveness without reasonable assurance of results.

Remember that the salesman of a stoker manufacturing concern can conclusively prove that any particular stoker is the best for your service.

DUPLICATE BELTS

In a color and paint factory there were in service a number of grinding and pulverizing machines. These machines were belt-driven, and because of the excessively hard service to which they were subjected, as well as the unfavourable working conditions, difficulty was frequently experienced with broken belts. The belts often broke open at the joints, when an abnormal stress was produced. As a rule, this resulted in the shutting down of the machine for a half-hour or so while the millwright was sought out and the belt fixed up and put back in service. These breakdowns usually tied up other operations, too.

The millwright finally hit upon the following scheme: He made up duplicate belts for all of the machines that gave trouble, fitted these belts upon the pulleys, and then took them off and hung them in closets adjacent to each machine. Then when the belt in service broke the machine operator had only to go to the closest, get out the duplicate belt and slip it onto the pulleys, involving a tie-up of but a few minutes. The broken belt was promptly fixed up by the millwright, and put back into the spare belt closet for future use.

While this plan ties up a little money, it eliminates delays in connection with the grinding operations, and can well be duplicated in other establishments where troublesome belts are found.—*Factory.*

The Fuel Problem

AN item in the news from Montreal discloses the fact that a shortage of fuel is causing great inconvenience there. Montreal uses large quantities of soft coal, which in the years before the war was shipped up the St. Lawrence in ample quantities to supply the needs and furnish a substantial reserve. In those days the methods of using coal which have largely contributed to the present shortage were very much in evidence, not only in that particular district, but all over the country where coal was used. During the strenuous days of the war a great cry for conservation was raised, and our Government came very nearly achieving something in the direction of teaching fuel users better methods.

With the passing of the high productive period of the war, the Government enthusiasm waned, and little more was heard of conservation from an official source. The mounting cost of coal and the difficulty of getting it is causing interest in this question again. The necessity for education of the men who are responsible for the proper burning of coal is as great as ever.

It is as true now as it was five years ago that the average efficiency of the steam plants in Canada would not reach the 50% mark. In some places it is feasible to use oil fuel, and the owner then comforts himself with the thought that he is getting good combustion efficiency. Perhaps he is, but it is just as easy to burn oil inefficiently as it is coal.

From the point of view of economy, and also the conservation of natural resources, it is time that a really comprehensive effort was made to make the problems of combustion better understood among the rank and file of power plant operators. It would well repay a group of manufacturers in a district to pool together and get a combustion expert into the district to personally visit each plant and set them in the right way. The saving that can be made in a steam plant by the exercise of a little care with no expense at all for instruments is enormous. We speak of the average plant, not of course of large installations where the best of scientific methods are in force. The average power house operator is anxious to do the best by the plant, and it is up to the owner of the plant to give him every facility.

If half the energy that is devoted to other forms of propaganda were to be put into this question of fuel efficiency, it would not be long before the country would be getting along with half its present consumption of coal. What is needed is a concerted effort, and representative bodies of manufacturers and engineers should get together and devise a programme of education that would cover the country. The question of expense need not deter them, because they will get it back a hundred fold. It will be a long long time before we can do without coal or oil fuel in this climate, and it will be a considerable time before the hydro-electric power entirely supplants steam, if it ever does. The more general use of the internal combustion engine will no doubt relieve the situation to some extent, and the installation of more economical steam engines is a factor in the right direction. The greatest source of waste is still the boiler furnace. and that is the place where the remedial measures should be applied in the first instance.

Culling Out the Weak Spots

SOME idea of the care needed in turning out special steel can be gathered from points brought out in a paper by Mr. De Mare, superintendent of the open hearth department of the Midvale Steel and Ordnance, Philadelphia.

Speaking of the tests made in armor-piercing projectiles, he stated:—

"From each lot of 500 projectiles, four are selected to be fired against a face hardened armor plate at a certain velocity and angle of impact of which two must pass through the plate and remain in effective bursting condition. Should this test be a failure, four more projectiles may be selected and fired, of which three must pass through the plate and remain in effective bursting condition. In the case of 16 in. shells, the cost to the contractor of this second test would amount to about $20,000. Should it fail, the whole lot of 500 projectiles may be condemned or the contractor may be permitted to retreat it and resubmit it as a new lot, which would entail an extra expense of approximately $100,000. It is thus evident that every possible attention must be paid to the quality of this steel, in order to avoid great financial loss, as well as loss in reputation."

There is a point here that could very well be brought out and emphasized, viz., that each piece is good or bad by itself. There is no such thing as an average.

Other lines of industry should get that idea. It would pay and pay handsomely.

A mechanic can work it, so can the foreman—so can the manager or owner.

Each day's work, each day's output can be put up against that simple standard.

The Engineering End of the Convention

By T. H. FENNER

A FEATURE of the C.A.S.E. convention that could hardly escape notice was the fact that the only engineering paper read before the delegates was contributed by a gentleman outside of the organization altogether. This paper, which was on a subject of consuming interest to every power plant engineer, found the assembled delegates completely unprepared to ask a question or offer a suggestion. In fact, it was very apparent, although the reader was thanked very heartily for his effort, that the members of the convention looked upon the paper as something to be laid aside to some future indefinite date, the immediate concern being to get on with the entertainment. Power House has called attention to this tendency of the convention delegates before, and though recurrence to the subject may not tend to popularity, yet we feel that something should be said on the matter.

There is no disguising the fact that a time is approaching when the stationary engineer, if he does not wish to be relegated to the position of a mere operator, has got to widen his vision, and get a more general idea of engineering matters. The art of starting up and stopping a plant is one that can easily be acquired by an untrained man in a very short time. The broad engineering education that will enable a power plant engineer to step into an owner's or manager's office and discuss power plant problems from a business point of view requires infinitely more. One would expect a gathering of representatives of an association that prides itself on its educational features, to have had some questions and discussions on the agenda that would have given a lead to every power plant engineer in the country, whether members or otherwise. Nothing of this sort took place.

There have been many defections from the ranks of the association during the past year, many of those dropping out having cast their lot with the union. While we have nothing to say against unionism, on the contrary, believing that the workman owes much of his advancement to a safe and sane use of union principles, we believe strongly that it is not in unionism alone that the best interests of the stationary engineer lie. The man who is earnestly working to advance himself to a position of importance and prominence in his chosen line of endeavor has nothing to gain from a union, but on the other hand, may easily find it a handicap. However, an association for the advancement of knowledge, and interchange of thought, offers him the kind of communion with his colleagues which he needs.

The C.A.S.E. was founded by men who earnestly wished and worked for the advancement of the stationary engineer. It has no more sincere well wisher than the writer of this article, but one cannot help feeling that in some way it has fallen short of its high endeavor. After working for years for a graded certificate act, the passing of that act was the signal for a howl of protest from a large number of engineers, many of them members of the C.A.S.E. who seemed to think that the passing of the necessary examinations was all right for the other fellow, but not for them. The lack of interest in engineering matters displayed at the convention is also a sign that there is something radically wrong.

The stationary engineer seems to be in a condition of apathy towards education. We say the engineers seem apathetic because in Toronto, where there is a free technical school right at their doors, but little advantage is taken of it. The C.A.S.E. has a golden opportunity to lead the way, and attract the younger men, who may reasonably be supposed to be imbued with ambition into their ranks. A broad and comprehensive scheme of education should be set under way, instead of the spasmodic attempts made by individual lodges. If the finances are hampered, the dues could very well be revised. The average man does not appreciate anything he gets too cheaply. If he has to pay a reasonable sum, he takes more interest and will want to know what he is getting for it.

To stimulate interest, for instance, why could not the Grand Lodge choose a subject, or number of subjects, for the members to write a paper on, and offer a prize to the best one. This paper should be in the hands of the executive at least three months before the convention, and be circulated among every lodge. Set a definite time at the convention for the reading and discussion of these papers, as is done at every meeting of any other engineering society. The C.A.S.E. says stationary engineering is a profession, not a trade. Well, then, let them conduct their deliberations in a professional manner, and set the lead to the others. The preparation of these papers would lead the competitors into a deeper research than probably any other method that could be tried.

It may perhaps be felt that Power House is pressing this subject unduly. Our reason is that we wish to see the stationary engineer become a bigger and better man, and that we believe the C.A.S.E. is the institution that can help him to help himself. Education is a duty the engineer owes himself, his family, his employer, and his country.

In the British Market

FOR the most part Canadian goods are well thought of in the Old Country markets. Britain has been for some time, and continues to be, our best customer when it comes to selling. In 1919 Canada sold to Old Country buyers $528,000,000 worth of goods, or 43 per cent. of the total amount of our sales.

Formerly the bulk of our trade to Britain was in raw materials or farm produce, but more and more we have been sending in the finished material, and it is getting a good reception in the British market. One firm recently went to a number of the larger stores in Britain to find out how the Canadian goods were received. In groceries, provisions, flour, rolled oats, bacon, cheese and salmon it was found that the Canadian article was considered as the standard of the trade. Strange as it may seem, our spaghetti and macaroni are competing with the article made in Italy for the London trade. It was hard to get a British dealer to admit that Canada, or any other country for that matter, could make jams to equal the Old Country product. Canned fruits were severely criticized in many particulars, although Canadian apples are acknowledged as being the best reaching the market.

Canadian made garden utensils, tools and garden furniture sell well and are popular. The Britisher is wedded to white enamelware, and in that essential the Canadian product, which is often finished with a grey or brown speckle, is lacking. They consider our tinware rather clumsy, but oil stoves compete with anything sent in from American makers. The Canadian kitchen range is perhaps a little too heavy and large for the British requirement.

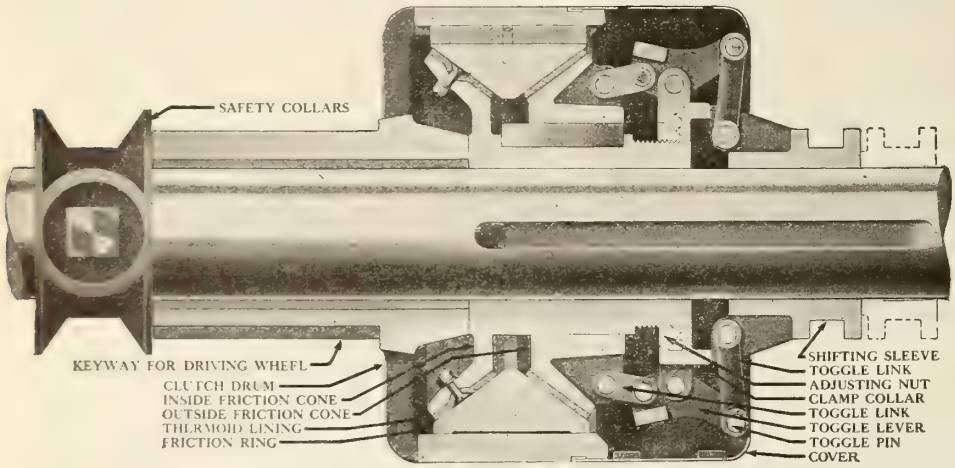
For electrical equipment there seemed to be a real opening for Canadian-made goods. Only a few lines appeared in the stores visited, but these had sold well against all competition. It must be remembered that there are many voltages met with in Britain, and electrical goods going in there should be of the universal type. Woodenware, kitchen cabinets, fibreware, etc., from the Dominion are acknowledged to be the best reaching the British buyer.

In spite of all that was said during the early stages of the war about Canadian-made shoes, there is a good sale for the Canadian article.

Progress in New Equipment

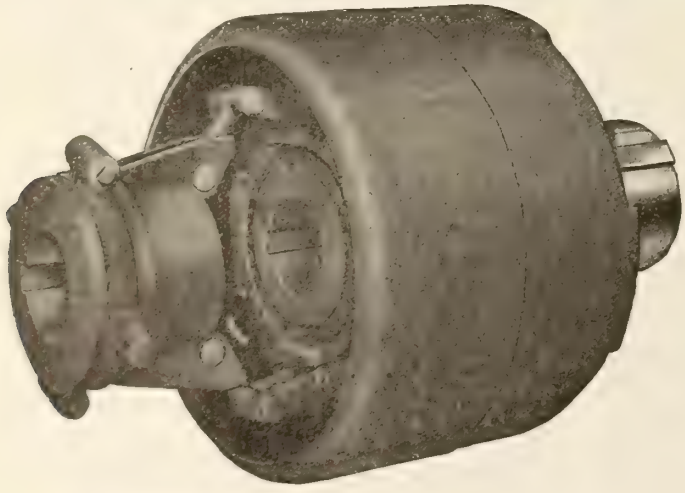
TWYNCONE FRICTION CLUTCH

The Link-Belt Co., 910 S. Michigan Ave., Chicago, Ill., have placed on the market what is known as their Twycone friction clutch. One of its exclusive features is that it has a one point adjustment. All moving parts are inclosed, making for absolute safety. The clutch is also perfectly balanced, this feature allowing it to run at high speed without causing it to throw in—or out.



SECTIONAL VIEW OF THE CLUTCH.

The construction is very simple. Moving parts are reduced to a minimum, and high speed does not affect its operation. The clutch has to be eased in when running at any speed, and the friction cones are lined with thermoid. Every part is easily accessible, and if necessary can be easily replaced. The accompanying photographs will still further show the construction and appearance of this new style clutch.

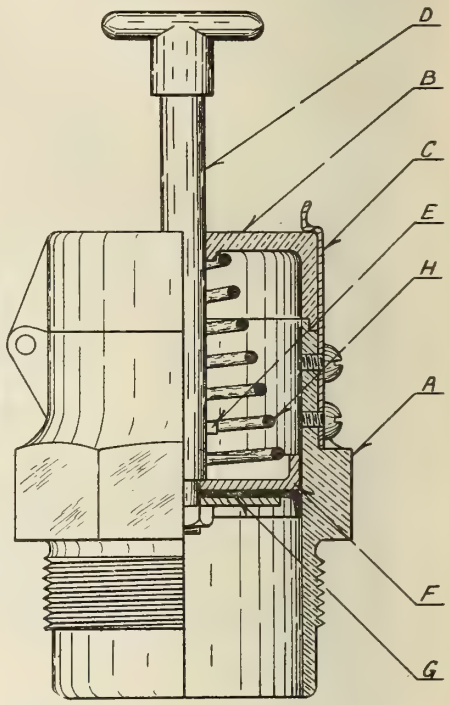


GENERAL VIEW OF THE CLUTCH.

AUTOMATIC GREASE CUP

The need of effective lubrication to bearings and all surfaces subjected to friction, has been, and probably always will be, an outstanding factor in engineering problems. The varied conditions under which many mechanisms are required to operate makes it imperative that ample facilities be provided for proper lubrication in order to avoid the inconvenience and even destruction that frequently follows from insufficient foresight in this connection.

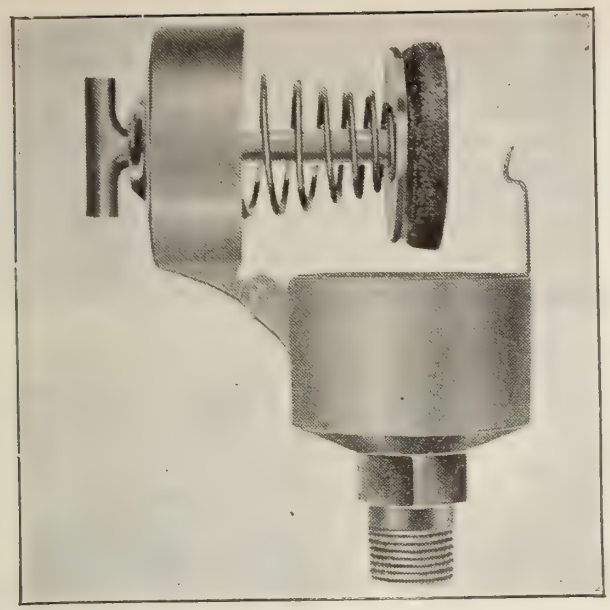
The illustrations depicted show a new design of grease cup which is automatic in its action, for when the cup is once filled and pressure applied, the feeding process is constantly maintained until all the grease has been delivered to the bearing. These grease cups are made in a variety of sizes and designs to suit any desired purpose or condition, the action of the automatic principle being identical in every instance. In Fig. 1 it will be seen that the body A is bored clear through, but the lower portion may be made to any desired shape and threaded to suit.



SECTIONAL VIEW THROUGH THE CUP.

The cover B is hinged to the body, and when closed is locked in position by the steel spring C. When filling the cup the spindle is raised to its extreme position, the small pin passing through a slot in the cover. A slight twist of the spindle locks it in this position and the cover is opened. It will be seen from the construction that the cover can only be swung open when the pressure disc F is retained within the cover. An accurate fit within the cylinder is maintained by the cupped leather washer G. The spiral compression spring H provided a steady pressure upon the grease in the cup so that an automatic feed to the bearing is always assured.

The action of this spring prevents the formation of a vacuum beneath the pres-



THIS SHOWS CONSTRUCTION OF THE CUP.

sure disc as the latter will follow the grease down as it is gradually delivered to the bearing. Suitable springs are provided for the different grades of grease. All parts are interchangeable on each size of cup so that separate pieces are available for any replacements. The cup may be inverted or located in any position without affecting its efficiency. These cups are adapted to locomotives, marine, gas or stationary engines, and all mechanical equipment where grease cups are used. These cups are made and sold in Canada by the Edward A. Robinson Co., 228 Craig St. W., Montreal.

PROMET BEARING METAL

HEAT treatment as a means of increasing the efficiency of steel has become a universal factor in engineering problems, but little knowledge has been acquired as to the heat treatment of non-ferrous metals for adding to their strength and durability. In Promet metal the manufacturers, the American Crucible Products Company of Elria, Ohio, have obtained a metal that possesses all the advantages that has been accorded to the bronze and other non-ferrous metals of olden days, when such metals contained all the tempering characteristics now possible only in steel tools. While the actual process used by the Egyptians of olden times will probably always remain a mystery, the results obtained in the making of Promet are in many respects identical with existing specimens of those pre-historic bronzes and other metals.

While the analysis of Promet is the same before and after heat treatment, the process undoubtedly changes a relatively good bearing metal into one of incomparable superiority in both bearing and lubricating qualities. The accompanying cuts will show the remarkable change in structure and the marked similarity to steel before and after treatment. It is claimed that the properties of this metal will remain permanent under any and all conditions; heating up to 2,000 degrees F., time or exposure, conditions of storage or long and exacting service, have no deteriorating effect upon the metal, and the metal can be remelted and re-used over and over again, and still retain all the advantageous qualities of the virgin metal.

It is also claimed that it has many times the bearing properties of any tin base babbit, and many times the lubricating properties of any lead base babbit. Many working tests have been made with material, and loads of 9,700 pounds per sq. in. have been carried without distorting the metal, and the co-efficient of friction is remarkably low, particularly where lubrication has been seriously neglected. It will melt at 600 degrees F., and can be heated to 2,000 degrees without the least injury. The recommended temperature for pouring is between 700 and 850 degrees F., and it is claimed that the metal is non-shrinkable when worked at this heat. An important feature of the metal is that it will not stick to the shaft when the bearing becomes overheated. Hot slag and molten metal cars, fitted with Promet, have shown no signs of wear after four or five months' service. Promet is equally adapted to high speeds and heavy loads. The Engineering Sales and Service Company, 55 St. Francis Xavier Street, Montreal, are the Canadian distributors.

MACHINE VISE

The Hoosier Drilling Machine Company, of Goshen, Ind., are now making a new line of machine vises. The jaws are of hardened steel, but may be modified to meet specific needs.

SINGLE-END DRILLING MACHINE

The Cadillac Tool Company, of Detroit, Mich., are placing on the market a single-end machine similar to the one recently designed for double-end tapping. The spindle feed is operated by a lever above the spindle head. The machine has a capacity of 17/32 inch drilling in steel, and may be provided for either belt or motor drive.

AERIAL GRINDER

The Van Dorn Electric Tool Company, of Cleveland, Ohio, are now building a small aerial grinder, which may be obtained for operating either with d.c. or a.c. installation. The grinder has a 12-inch extension that carries the wheel well out from the frame. Ball bearings are used throughout and grease lubrication is provided.

RE-DESIGNED SHAPER

The re-designed 20-in. crank shaper of the R. A. Kelley Company, Xenia, Ohio, incorporates many improvements over the old design. The machine is constructed for either belt or motor drive. The link connection from the rocker arm is such that the ram is forced on to the bearings, which helps to neutralize the upward thrust of the tool. The apron is so mounted that it may be completely rotated. Table is located by means of a hardened taper plug. Ball bearing thrusts are provided for elevating the screw. A special feed box is fitted to the end of the cross rails, and the amount and the direction of the feed may be controlled without touching any moving part of the machine. Feed is automatically disengaged at the end of the travel. Helical teeth are used on all gears and pinions.

CATALOGUES

We have received a catalogue illustrating the Stowe Stoker, manufactured by Laclede Christy, St. Louis. The booklet is well illustrated and contains much detailed information on the stoker. The Stowe is claimed to be a progressive fuel stoker, and as such, differing from both the under and over feed types. The advantages claimed for it are well set forth in the catalogue.

The Barnstead Still and Sterilizer Co., of Boston and Chicago, have issued a bulletin descriptive of their water purifying apparatus. Besides the descriptions of the various types of units employed for different purposes, some useful information on the chemistry of water is given. The machines include types suitable for industrial, laboratory, domestic, and special purposes, such as hospitals. A list of users and a number of letters from purchasers expressing their satisfaction are included.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

REFRIGERATION

Question.—I have a few questions regarding an ice machine that I have to take care of. It is a small York machine and I would like to know how to purge the condensing coils, these being the high pressure coils. There is a needle valve located on the top of these coils with an outlet to the atmosphere. If I shut machine down to stop the flow of gas in the discharge would the air raise to top of coils to be blown off? There is no other outlet on coils except inlet for charging system with ammonia at end of condenser bottle.

How many pounds of calcium will be needed to raise a chloride of calcium test instrument one degree on same, and does this apply equally the same for each degree as the brine gets stronger?

What is the most practical method for dissolving the chloride of calcium, that is, when a full charge has to be mixed for a brine tank?

Answer.—The purge valve on the top of the condenser coils is the proper place to get rid of air. It is usually best to blow into a pail of water by means of a hose connected to the purge pipe. The air will bubble up through the water, the stopping of the bubbles being the signal that all air has been blown out. Another method is to allow all the ammonia to drain to the low pressure side of the system. The valve between the high pressure coils and expension coils is shut, and the discharge and suction valves on cylinder shut. The by pass between the discharge and suction pipes is then opened, and the purge valve on the cylinder. If the machine is now started, all the air will be pumped from the high pressure side. When a vacuum shows on the gauge, stop the machine, close the cylinder purge valve, and allow the pressure to equalize on the system through the cylinder stop valves. The air will then be got rid of. The condenser should always be cooled down before purging.

The following table will show the amount of chloride of calcium required at various points from 0 to 100 on the salometer.

The best way to dissolve the calcium chloride is to put a steam jet into it from a steam hose.

TABLE—CALCIUM CHLORIDE BRINE.

Degrees on Salometer	Lbs. C C per gal.	Freezing point Degrees F.

A RUPTURED TUBE IN WATER TUBE BOILER

To a great many engineers who have not been fortunate enough to have the chance of handling or operating large units, the thoughts of them are mingled with a certain amount of trepidation and awe. I speak from experience, there was a time when I felt the same way. My idea of writing the following experience was brought about by Mr. Coombs' paper on "Modern Boiler Practice," in which he deals with one of the large units now running at the Power House named. When these units were first installed our firemen rather stood aloof and I am afraid that a certain amount of fear was felt by them and more especially after the accident which is described later.

The accident in question occurred about five weeks after the boilers had been in operation, and took the shape of a burst tube, the picture of which I enclose so that all the readers of Power House may see that it was not an ordinary split tube, but a complete burst. The sound of the explosion was more like the bursting of a guage glass than anything else. If readers will look in the May 20th issue on pages 228 and 229, Figs. 5 and 6, the fourth tube from end facing reader, is where rupture occurred. The boiler at the time of the accident was evaporating 46,000 lbs. of steam per hour, at least that was as far as the flow meter hand could go. How much more it is impossible to say, because an enormous body of water came over the header rupturing the

PHOTO OF SPLIT TUBE

joints and stretching one set of bolts at the last elbow about 3-16 of an inch and then almost brought the turbine to a standstill. I can say without exaggeration it was about the busiest 15 minutes I ever spent in my life. Just picture to yourself, reader, if you can, one minute everything going rosy and next minute, without any warning, Bang! the engine room was flooded with steam. I made my way through the steam to the boiler room, but was met with worse conditions, not only blinded with steam but over two inches of boiling water on the floor. We raised the stoker doors of the boiler (as we guessed what had happened), by myself and another getting near the boiler where the water was pouring through the iron casing, and receiving a warm bath.

However, after raising the stoker doors we placed the fire hose on the fire. It's all very well to say close the dampers, or smother the fire with ashes, but try and think how much coal there was on the grate heated to a state of incandescence. The grate was carrying 5" fire at the time. This would work out

at 224 ft. by .417=93.4 cubic feet of coal, now the Admiralty regulations call for 40½ cubic feet per ton, in stowing this=2.3 tons at a temperature of 2,800 deg. F., of course, there would not be that amount of hot coal in ordinary times, but the boiler was being forced and a large amount of unburnt coal was piled up against back wall, which more than out-balances the green coal just entering the stoker door, but I am wandering away from the subject. We kept the emergency feed wide open, and as the steam commenced to disappear we found the poor fireman lying down with all his clothes literally blown off his body. Well, I draw a veil over that, as the sight is not good to remember. After normal conditions had been restored and the boiler opened up, the ruptured tube was discovered and the tube had laid itself over the tube at each side of it, striking it so hard as to loosen them from the upper headers.

Now comes the query for the engineering world to answer: Why did that body of water come over the header when the tube burst?

A few solutions from the readers of Power House would oblige the writer.

—H. WRIGHT.

CORRESPONDENCE

The Editor, "Power House,"
Toronto.

Dear Sir,

The writer has received numerous requests from engineers for an interpretation of a paragraph in the new regulations for stationary engineers, and the writer believes that if a ruling were obtained from the board of examiners and published in your journal, it would relieve a great amount of uncertainty.

The paragraph in question is respecting: "Partial Operation of Plants at Night," page 17 in the 1919 issue of the regulations.

At first sight it would appear that it is necessary for a plant over 300 B.h.p. to be partly operated by a second class engineer at night. However, the regulations state " . . , said plant may be operated by an engineer holding a certificate one grade lower than would be required by the Act if the same was in full operation."; and under the conditions of the preceding paragraph, i.e., where a plant is operated in two or more shifts under a chief engineer, only the chief need hold a certificate corresponding to the grade of the plant, and an engineer holding a certificate one grade lower may take charge of a shift, under full operation, when the chief is absent Thus, for partial operation an engineer holding a certificate one grade still lower than shift engineer under full operation is required, or a third class engineer may partially operate at night a first-class plant, or a fourth class engineer may partially operate at night a second class plant. The above is the interpretation put upon the above paragraph by the writer, but a ruling by the board of examiners would be welcomed.

Notwithstanding the fact that the board may give a ruling on the above, there is nothing in the Act specifying that the board shall have absolute power in the interpretation of the regulations, and any prosecutions under the Act would therefore be decided by the trial judge according to his own interpretation of the regulations, and the writer believes that the above interpretation is the one which a judge would be most likely to make.

Yours very truly,
M. B. WATSON.
Director, Dept. of Engineering,
Toronto Technical Schools.

Editor of "Power House."

Dear Sir,—We are very much interested in the communication of Mr. J. G. Kingston on page 297 of your issue of June 21. In this communication Mr. Kingston calls attention to the advisability of having inspectors appointed by the school boards and city councils to make a study of combustion of coal, and make such changes and improvements in boiler plants of public buildings to conserve the supply of coal.

This very thing is being done by all of the larger municipalities in the States where, as a rule, chief engineers are appointed by the school boards to make a study of the different problems in connection with boiler room practice in the power plants of these public institutions. With coal at its present prices there is a very large field for this work, and immense savings can be accomplished by properly educating the firemen and by installing the proper kind of furnace equipment. In the larger cities the boilers in all schools and public buildings are equipped with stokers, which effect savings in the amount of fuel used of from 10 to 25 per cent. The intermittent firing by hand is naturally very wasteful, while the stoker, which feeds continuously, overcomes this waste. Many makes of stokers are equipped with magazines of considerable capacity, so that these magazines can be filled with sufficient coal to run the stoker for periods of an hour or more before the magazines require refilling. This gives the engineer an opportunity to attend to other duties and does not require his constant attention and care as is necessary with a hand-fired furnace.

Another very important matter to be taken into consideration is the fact that school buildings are installed in residential districts where the elimination of the smoke nuisance is a very important factor. Continuous, even firing of a stoker practically eliminates all smoke, which cannot be accomplished by hand firing unless the most expert firemen are employed to give the firing their constant attention.

We think the points brought out in Mr. Kingston's article are very well taken and that the savings that can be accomplished by the employment of an engineer to make a study of these matters amount to a great deal more than his salary—even in the smaller municipalities.

DETROIT STOKER COMPANY.

INTERNATIONAL STANDARDIZATION OF WIDTHS ACROSS FLATS ON NUTS AND BOLT HEADS

The Swiss Standards Association has addressed a communication to the national engineering standardizing bodies of the various countries, proposing the international standardization of the widths across flats on nuts and bolt heads.

The proposal covers the range of ¼ in. (6 mm), 3 in. (80 mm), diameter of bolts. The numerical values proposed are a compromise between the United States Standard, the British, or Whitworth, and the metric "Systeme Internationale." The communication states as follows:

"If at this moment the parties concerned were willing to do their best to bring about an agreement, a satisfactory international standard could be attained, while, when nationally individual standards would be introduced into practice, an attempt to reach an agreement could hardly be expected to be successful. We hold it advisable to subject the matter to a referendum of widest possible scope. It seems to us that by generous cooperation we ought to be able to find some system, which could induce France to agree upon, and at the same time form a foundation which would render possible the adoption by America and England.

The V. S. M. Committee of Standards being ardently urged by the Swiss industry, is compelled to decide upon a system of widths across flats in the near future, but doesn't care to do this unless one more attempt to bring about an international agreement in this matter be made by the V. S. M. Bureau of Standards." The communication was addressed to the standardizing bodies of America, Belgium, England, France, Germany, Holland and Sweden.

The most novel application of electricity to industry is the purification of clay. A machine designed for this purpose was recently exhiited before the Royal Society, London, England. It consists of a trough with a cylinder which slowly revolves over a grating through which the "slip"—a mixture of clay and water—is forced. When the cylinder is connected to one pole of an electrical circuit and the grating to another, the electrical effect separates the fine particles of clay from the water and deposits them on the cylinder, whence they are removed by a scraper. By this simple and ingenious process, known by the name of "electrical osmosis," low grade and dirty china clays can be used to produce pure fine clays for pottery and for the manufacture of "art" paper. The clays used for fire-clay are made more plastic and also more fire-resisting as a result of the electrical treatment. The same process can be applied in tanning leather and in the preparation of glue and gelatine.

NEW VICE-PRESIDENT

Mr. C. J. Brittain, formerly managing-director of the Winnipeg, Calgary and Saskatoon branches of the Canadian Fairbanks-Morse Co., Ltd., has been appointed vice-president and general sales manager of that organization, with headquarters in Montreal. Mr. Britfain succeeds Mr. C. Graham Drinkwater, who has been vice-president in charge of sales for many years, and who has resigned to join the banking firm of Aldred and Company, Ltd.

G. J. BRITTAIN

Mr. Brittain brings to his new post a wide experience of many years and a splendid record of achievement. He was one of the first salesmen engaged by the Canadian Fairbanks-Morse Co., Ltd., in the early days of the company, and he has made good in every position to which he has been appointed. He has the entire confidence and hearty support of all those who know him, both in the organization and as customers.

Mr. Kenneth Forbes, who has been manager of the St. John, N.B., branch, goes to Winnipeg to assume charge of that branch, together with that of the Regina branch, which is under construction at the present.

Mr. Forbes is succeeded at St. John, N.B., by Mr. W. J. Hill. Other changes in the management of the sales department—all of which represent well-earned promotion and increased opportunity to assume greater responsibilities—are the appointments of Mr. Malcolm Cordell to be Montreal manager, and Mr. George L. Nies and Mr. Archibald Turnbull, who will become managers of the Calgary and Saskatoon branches respectively, taking on a portion of the duties which formerly came under the direction of Mr. Brittain.

The Economy Fuse & Manufacturing Co., of Chicago, manufacturers of "Economy" renewable fuses, announce the appointment of Mr. F. L. Easton as district sales manager of their Denver office, 205 Commonwealth Bldg., Denver, Colorado. Mr. Easton succeeds Mr. R. M. Olsen, who resigned recently. Mr. Easton formerly was connected with the Economy Fuse & Mfg. Co., but more recently has been doing sales promotion work for the Gates Rubber Company.

U.S. AND CANADIAN FIRMS COMBINE

On April 2 the stockholders of J. H. Williams & Co., manufacturers of drop-forgings and drop-forged tools at Brooklyn and Buffalo, N.Y., and of The Whitman & Barnes Mfg. Co., makers of twist drills, reamers, wrenches and drop-forges, at Akron, Chicago and St. Catharines, Ont., ratified the agreement providing for the consolidation of the wrench and drop-forging plants and business of Whitman & Barnes at Chicago and St Catharines, with J. H. Williams & Co.; The Whitman & Barnes Manufacturing Co. retain their twist drill and reamer business and will continue as an entirely separate organization and on an extended scale, the manufacture of these tools at Akron, Ohio.

J. H. William & Co. have long been known as the largest manufacturers of drop-forgings and drop-forged tools in the world, and was one of the first to enter this field commercially. The business was founded in Flushing, L. I., as a partnership in 1882 by James H. Williams and Matthew Diamond under the style of Williams & Diamond, later Williams & Brock. It located in Brooklyn in 1884, assumed its present name in 1887, and was incorporated in New York State in 1895.

The company is widely and favorably known, not only for its special drop-forgings made to order, but also for the quality of its catalogue product, drop-forged wrenches, "Vulcan" chain pipe wrenches and vises, lathe dogs, clamps, and numerous other standard lines of drop-forged tools. Many of these were originated and patented by the company. At the successive World's Fairs at Chicago 1893, Paris 1900, St. Louis 1904, and San Francisco 1915, the company's products in each case received the highest award in their field.

The Brooklyn works employs about 750 persons, occupy two adjoining square blocks of city property, including the street between, which is closed, and contain about 197,000 sq. ft. of floor space. In 1914 the Buffalo works, an entirely new plant, began operation; they now employ over 1,000 persons and comprise 47 acres, with about 233,000 sq. ft. of floor space.

The Whitman & Barnes Manufacturing Co. was founded as a partnership in 1846 by Augustus Whitman and Alfred G. Page under the title, Page, Whitman & Co. In 1868 the Akron factory was built, and in 1877 the business was combined with that of George Barnes & Co., of Syracuse, N.Y., the enlarged concern assuming its present name, The Whitman & Barnes Mfg. Co. The St. Catharines plant was acquired in 1882, and eleven years later the Chicago works were built. They now consist of forty-five acres of land, with 320,000 sq. ft. of floor space, and are connected by private trackage with four railroads. They employ about 800 people.

The St. Catharines works manufacturing special drop-forgings to order and standard lines of drop-forged wrenches, pipe wrenches, adjustable wrenches of various styles, pliers, hammers, hatchets, sledges, etc., are located on the Welland Canal and obtain power therefrom. They occupy about 2½ acres with floor space of 35,000 sq. ft. The company owns some six acres of additional property, which may be utilized in the near future for the erection of larger and improved facilities to care for the Canadian trade. This business has the distinction of having every jobbing house in the Dominion on its books. About 200 persons are now employed.

Two of the works, that at Buffalo and the new forge shop, 500 by 100 feet, and 3,000 h.p. power house at Chicago are the most up-to-date forging plants in the world, while those at Brooklyn and St. Catharines are admirably adapted to the tool-making end of the business.

Through this consolidation of the four plants, Brooklyn, Buffalo, Chicago and St. Catharines, the ultimate geographical ideal for the service of customers has been attained. The merger also emphasizes the leading position of the company in the manufacture of drop-forgings and drop-forged tools.

The company has been particularly fortunate in its relations with its men. Operating throughout its history on the principle of the highest wages in the industry for the most efficient work, supplemented (but not substituted) by expenses liberally incurred to provide the best possible working conditions, it has succeeded in establishing a relation of mutual confidence that has frequently been the subject of comment in the industrial and social press—in 1912 this was the cause of an unsolicited visit from Theodore Roosevelt, followed by a special article by him in "The Outlook" on the subject.

The Brooklyn factory, in 1893, had the distinction of being the first factory in this country to provide shower baths for its workmen, and again, in 1914, of leading its industry in the establishment of separate pension and life insurance systems for the direct benefit of its employees, and, of course, for the indirect benefit and satisfaction of its stockholders.

The business will continue to be operated by those who have been continuously identified heretofore with the business of J. H. Williams & Co., and with the Chicago and St. Catharines plants of The Whitman & Barnes Manufacturing Co., the organization being as follows: President and managing director, J. Harvey Williams; vice-president, A. D. Armitage; secretary and treasurer, W. A. Watson; controller, R. S. Baldwin; general sales manager, F. W. Trabold; Eastern district sales manager, A. S. Maxwell; Western district sales manager, W. E. Rowell; Buffalo district sales maanger, J. C. Cotter; Detroit district sales agent, A. M. Thompson; publicity manager, Hugh Aikman; general works manager, Capt. W. N. McMunn; chief engineer, Willard Doud; superintendent Brooklyn division, R. J. Smith; superintendent Buffalo division, T. F. Du Puy; superintendent Chicago division, Barney Nelson; general purchasing agent, J. C. Scanlon; general traffic manager, J. B. Payne; Canadian manager, W. J. Elliott.

ORGANIZATION CHANGES OF WESTINGHOUSE ELECTRIC INTERNATIONAL COMPANY

Several appointments have been made in the organization of the Westinghouse Electric International Company. At East Pittsburgh they are as follows: H. F. Griffith, assistant to general manager; R. W. Everson, manager of merchandising department; H. C. Soule, manager apparatus department; and H. S. Rizensteiz, manager price department.

In New York they are: G. H. Bucher, assistant to general manager; J .H. Payne, supervisor of agencies; and F. M. Sammis, manager of incandescent lamp department.

A. B. Cole, assistant manager, Department of Publicity, Westinghouse Electric & Manufacturing Company, has been placed in charge of the advertising and promotion work for the Westinghouse International Company.

The following men have been appointed sa foreign managers of the Westinghouse Electric International Company: F. M. Rodgers, of London, England, European manager; J. W. White, Royal Bank of Canada Building, Havana, Cuba, manager for Cuba, and L. T. Peck, Bartolome Mitre, 754, Buenos Aires, manager for the Argentine.

WESTINGHOUSE CATALOGUE OF INSULATING MATERIALS AND SUPPLIES

Miniature catalogue No. 5-A-1, giving a complete list of all insulating materials and supplies, has just been issued by the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa. Included in the list of products described are: mica, Micarta and Bakélite Micarta plates and tubing, treated and untreated cloths and papers, insulating and soldering compounds, insulating oils and tapes.

STOKER MANUFACTURERS ASSOCIATION MEETING

At a recent meeting of the Stoker Manufacturers Association held at Lakewood, New Jersey, the following officers and executive committee were appointed: Sanford Riley, president; M. Alpern, vice-president; A. G. Pratt, treasurer; S. A. Armstrong, and H. A. Hatton; J. G. Worker, secretary.

This committee is to meet in New York at an early date to name the standing committees of the organization for the coming year. A vote of appreciation and a round of cheers was tendered to P. A. Poppenhusen, the retiring president.

When asked for a statement after the meeting regard to his policies for the organization during the coming year the newly-elected president, R. Sanford Riley, made the following statement:

"I have always believed that the stoker business is a good one, but it has not even yet taken its proper place in the business world. I have seen it develop from a very crude business, conducted on a comparatively low plane, to a large business conducted on a much higher plane. We are getting an increasingly large percentage of able men in the business, which makes it good, not only for those in the business but also for our customers. After all, we can profit only as we serve, and the service possible by our business is one of the greatest in any line of business.

"We are no longer the leading propagandist in the art of conserving fuel. The Government seems to have taken over the position, and all we have to do now is to live up to the demands made of us.

"Our field is being enlarged every day by economic pressure, and my hope is that we, as an association, may conduct ourselves so as to be worthy of the field."

BOILING POINT OF AMMONIA

A subscriber asks us what is the boiling point of ammonia. This question is somewhat vague. The boiling point of anhydrous ammonia, such as used in the compression system of refrigeration, is 28.5 Fahr. while that of aqua ammonia is 146 Fahr at atmosphere pressure, and a specific gravity of .95.

One of the most important developments of electric welding in Great Britain lies in its application to building construction. The steel roof of a large factory recently erected in London was entirely welded, not a single rivet being employed. Each truss was completed on the ground, the various sections being merely laid in position and welded with mild steel by the arc process. When a truss was completed it was hoisted into position and welded on to the steel supports. The whole process of erection can be carried out much quicker than when riveting is employed, and there is also a great saving in material.

Great interest has been aroused in Great Britain by announcements concerning a textile material called "cotton substitute." It is not, however, a new thing, but its revival at the present time is due to the advancing price of raw cotton. It was invented ten years ago by a British engineer, and is a result of a special process of treating "china grass." By steeping the grass in certain chemicals the inventor obtains a fibre which can be spun in ordinary cotton spinning machinery. The resulting material takes dye readily, has a good lustre, and when mixed with cotton yarn produces a hard-wearing fabric. Apparently the only objection to it is its hairiness and harshness, but for certain purposes these qualities would not prove a serious drawback. Experts consider that its main value will be as a union fibre with cotton and wool.

INTERESTING BOOKLET

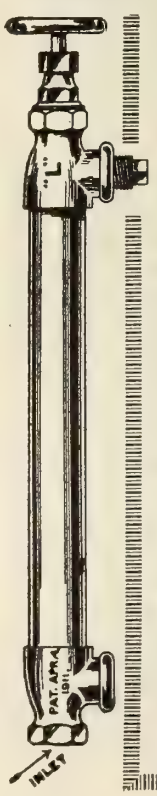
The Silver Mfg. Co., Salem, Ohio, have issued an interesting booklet entitled: 'Silver Drills in Service." It is out of the ordinary run of material and really tells a story of service of the Silver drills at the American sector of war. The tale is told by H. D. Parker, who was a First Lieutenant in the Ordnance Department, and we are told that a copy of this booklet will be forwarded to anyone interested.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done — give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.

Use The LONG STEAM for TRAP SATISFACTION



kettles, separators, steam mains. Works against 1 to 200 pounds pressure. Has two outlets and is installed in any position. DOESN'T FREEZE.
The Hamilton Powder Works, Beloeil, P.Q., use them with great success. Read this letter.
Dear Sir: We have used one of your steam traps for a long time and have found the same to answer the purpose as well as any seen in operation. We were so pleased with the working of this steam trap last winter that we ordered six more this season and have fitted them up at various points in the works where live steam is used for heating purposes.
(Signed) J. Murray Wilson,
Superintendent
Our trap will give you the same satisfaction as recorded above. Investigate and you'll be satisfied, too.

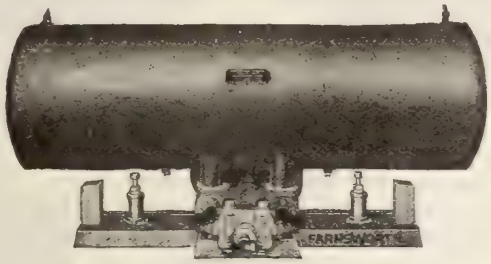
A Real Canadian Boiler Feeder

THE BEST IN THE WORLD

Ask the Canadian Farnsworth Company about these machines for your steam plant. We build boiler feeders from 20 to 1,000 H.P. each.

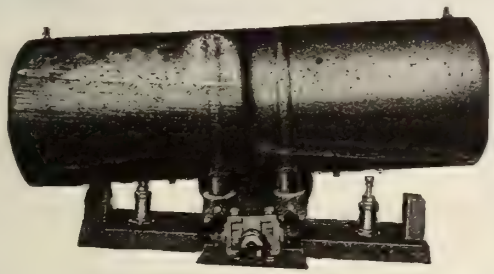


The Farnsworth "Duplex"

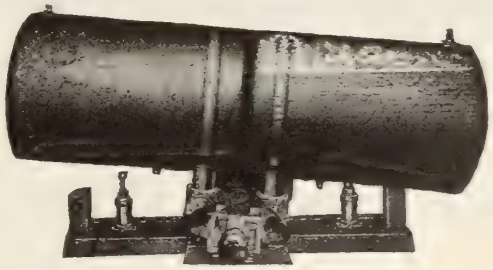
Our Engineers will give you expert advice on boiler feeding and condensation problems. No plant too large.

This Machine is the Product of Canadian Brains and Skill—Made in Canada by Canadian Engineers—the Last Word in Efficiency.

Study the Construction of this Machine.
Have you ever seen a Simpler Machine for the Purpose?
Everything designed for simplicity.
Least moving parts of any boiler feeder on the market.



No springs—No levers—No weights—No check valves to give trouble. Nothing to adjust. No necessity for adjustment. No trunnions, or bearings to bind and stop the action, or leak, and mess up your boiler room.



No open vents to waste your steam—A mechanically perfect Duplex steam valve—Can't leak and can't stick—No renewing of faulty discs.

Study the action of this machine—You have seen the common Return Trap in action—You have seen it "Hold up" the return lines—You have heard it "Pounding" and seen it blow steam through the open vent.

An open vent will waste at 50 lb. pressure about 15 H.P. per hour of your steam—Surely an expensive proposition.

Our Duplex boiler feeder or pump can't waste steam—It's a complete closed loop system, impossible with the common return trap.

Gives a continuous flow to boilers—Continuous drainage from heating apparatus—Continuous equalization between boiler and apparatus.

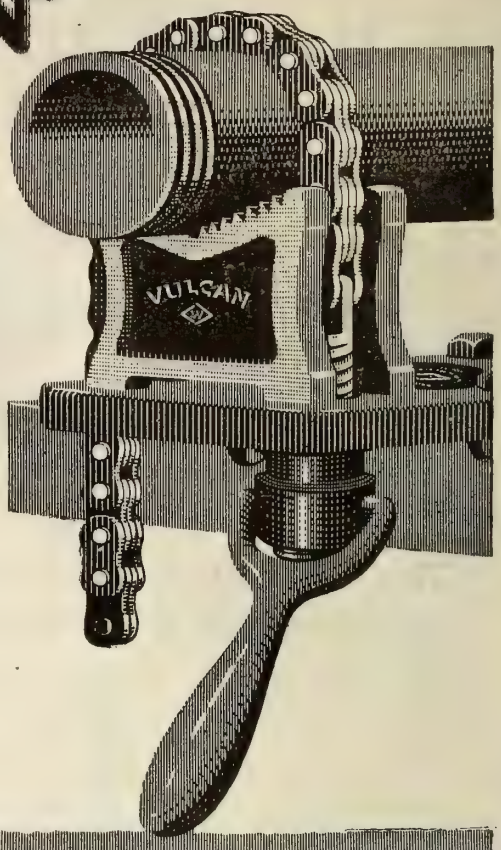
WILLIAMS' "VULCAN" DROP-FORGED CHAIN PIPE VISE



A PIPE vise, like any tool intended for rough usage, should be so designed and constructed that the severe strains and stresses of hard, continuous service cannot cause breakage or failure in operation.

Williams' "Vulcan" Chain Pipe Vises have no weak parts to fail through faulty design. Though they are far lighter and cost less than the conventional cast pipe vise, they are unbreakable. These Vises are made entirely from wrought metal, tested in our Laboratories before use. Each Chain is hand made.

Nothing that engineering experience and technical skill can suggest to improve them is omitted in their manufacture. All are backed by our unconditional guarantee.

Three sizes for ⅛ to 8" pipe. Booklet on request.

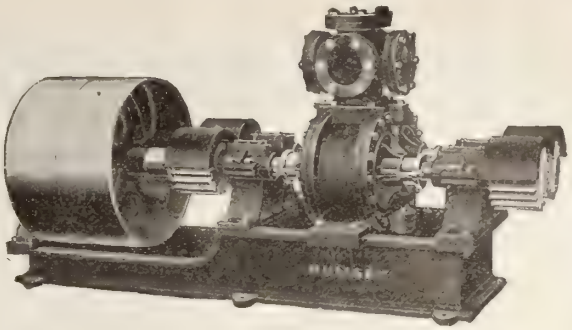
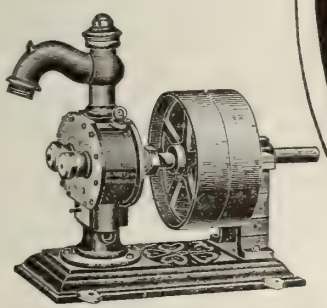
Rumsey Electric Rotary Fire Pump. Designed for general service as well as fire duty; 100 pounds pressure for fire service, and 75 pounds pressure for general service is recommended.



Rumsey Power Rotary Force Pump, for elevation up to 170 feet and pressures up to 75 pounds. Designed for water supply, oils or special liquids and for general pumping in mills and factories wherever a moderate priced pump of large capacity is desired.

RUMSEY ROTARY PUMPS

SENECA FALLS, NEW YORK



Rumsey Rotary Power Force Pump. An inexpensive pump of large capacity for handling water, oil, paint, varnish or special liquids. This pump is in big demand in industrial plants of all kinds and is suitable for elevation up to 80 feet.

Rumsey Rotary Power Force Pump. Very small; designed for pumping lubricants for cutting tools or monitor lathes, pipe, threading machines, bolt cutters, etc., also to return oil to reservoir from drip pan under machines, and for any work where a light-duty machine is required.

Sectional View of Heavy Service Rotary Pump, showing the arrangement of the packing strips with which the toes of the cams are provided.

Used in mills and industrial plants for general water supply, pumping to sprinkling systems, handling special liquids and for fire protection.

RUMSEY Hand and Power Rotary Force Pumps will handle almost any liquid that will flow—water, oil, paint, varnish, gasoline, grease, tar, ink, extracts, sizes, soaps, chemicals and commercial liquids of all kinds—liquids of a gritty nature, or those that have a chemical action unsuitable to iron or bronze excepted. The compactness and convenience of Rumsey Rotary Pumps, their large capacity and low cost make them the preferred Pump for all kinds of general pumping.

Improving Our Service

THE Directors of the Canadian Press Association decided last year that the MacLean Publishing Company was the largest and most important newspaper organization in Canada and must therefore pay the highest annual fee to the Association. The Montreal **Star** with its two big weeklies comes second, but the **Star** group had been doing business for 18 years before the MacLean Company began. While we have not the details upon which the Press Association based their decision we understand they figured that the MacLean Company had a larger advertising revenue. This is not the case. Lord Atholstan's properties probably carry a third more advertising, use more paper and have a greater total circulation. The MacLean papers on the other hand get more revenue from circulation; have to pay perhaps three times as much in salaries and wages and show considerably less profit.

Extra good service to readers first and advertisers next has been the cardinal principle upon which Colonel Maclean has built during these 33 years. In this work every man, woman and junior apprentice on our staff has had a share. We have tried to gather about us and train the best experts in the country. Here is the latest example of what we are doing:

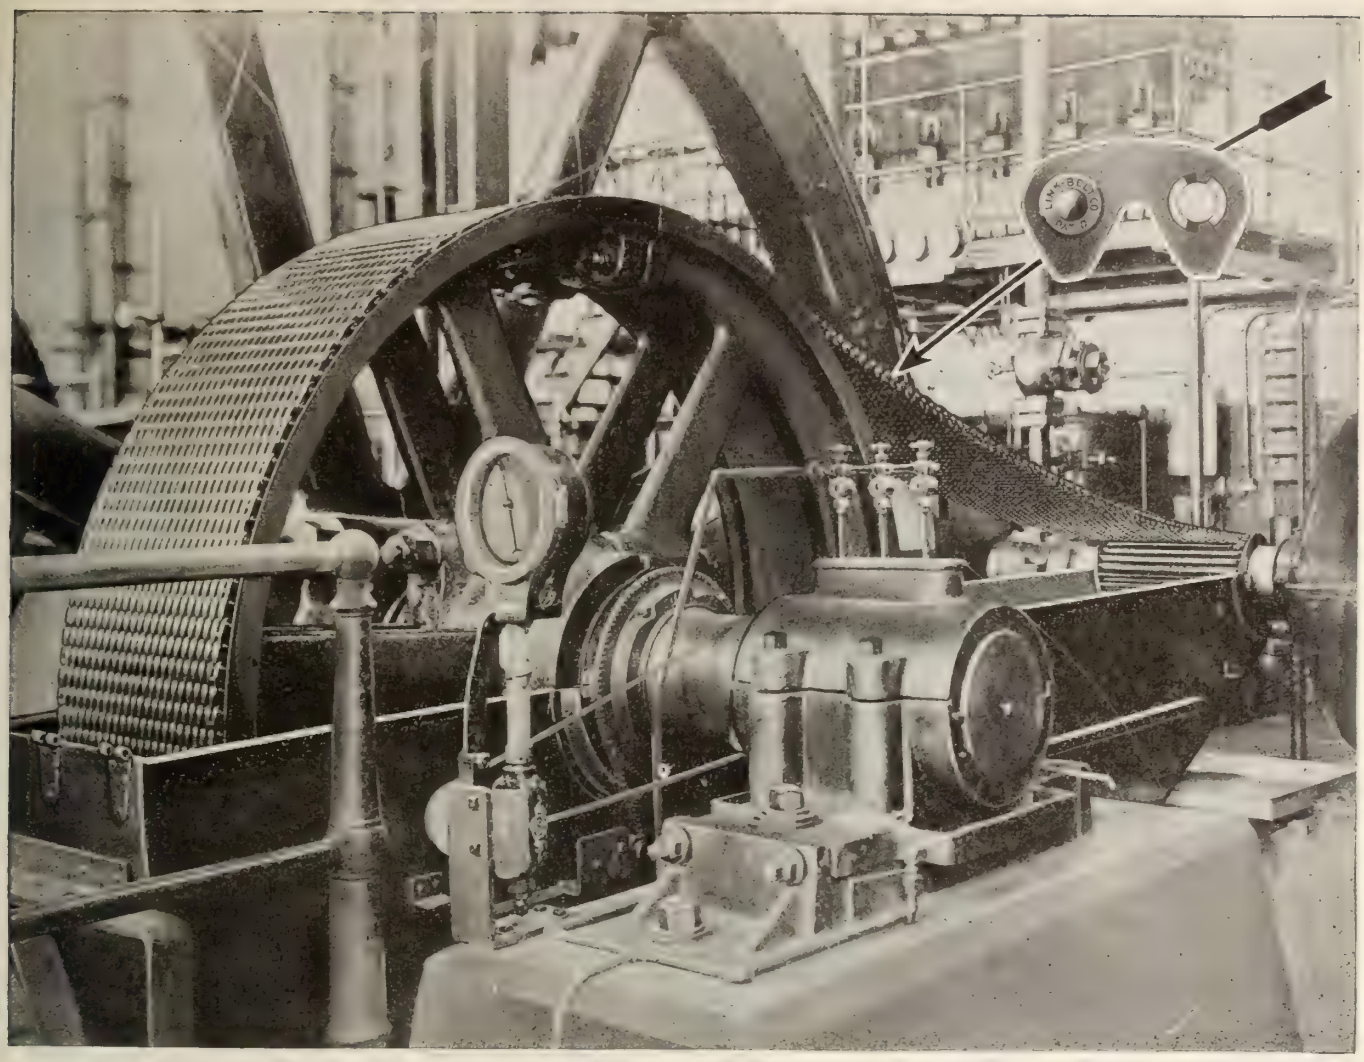
In the recent annual examinations of the Toronto Technical School, session 1919-20, in the Typography branch—that is the department where they learn how to set type—only 27 boys out of the whole city passed, of whom 10, or nearly 38 per cent. were boys of our own Composing Room, while in two out of the three classes MacLean boys stood at the head.

Several of our papers are the best of their class in the world but we are still far from satisfied with the service we are giving. As we can afford it, as the country grows, as our business grows, the service will be improved. We ask our readers to take these Technical School results as an evidence of our efforts to serve them better and better, for by giving a superior training to these boys we are laying the foundation for the still better work we hope to do in the future.

Readers can help us to give them a better service by sending in—direct to the President, Vice-President or General Manager—criticisms and suggestions.

POWER HOUSE

Montreal Toronto Winnipeg Vancouver



MODERN Science believes that, some day, Industry will draw its power directly from the sun. Science is probably right. But, in the meantime—

Business Science has to solve immediate problems, as, for instance, the problem of efficient and economical transmission, by mechanical means, of power developed by mechanical means.

And this can be, and is being, done in a scientific way—with Link-Belt Silent Chain Drives.

This method of transmitting power is as far advanced from the methods of Yesterday as Modern Science is advanced from the Science of the day of Columbus.

Witness above a 275 horsepower Link-Belt Silent Chain Drive, operating in the refrigerating plant of the Burgess Sulphite Fibre Company, at Berlin, N. H.

Link-Belt Silent Chain is Flexible as a Belt, Positive as a Gear, More Efficient than either.

It delivers 98.2% of every unit of power developed.

It operates smoothly, surely, at the highest speeds. It is steel-encased, protected from dust, and safeguarding workmen, and is lubricated by a constant oil bath.

It represents the highest achievement of power transmission engineers. It is the Ideal method of driving all types of machinery.

COPPUS TURBO BLOWERS EFFECT STEADY SAVINGS

In the modern plant of the New York Ice Company, New York City, this 22" COPPUS Turbo Blower has been saving time, money and labor ever since installation in April, 1917. It has **made possible** the use of cheap fuel, and **made sure** the maintenance of constant steam pressure. So satisfactory has been the service of this COPPUS Blower that two more blowers have since been purchased for other plants of the New York Ice Company.

COPPUS Turbo Blowers are cutting down fuel costs and keeping up steam pressures in cold storage and artificial ice plants all over the country. Automatically regulated, self-oiling, quiet-running—COPPUS Turbo Blowers are by far the most efficient means of securing mechanical draft.

Let our engineers tell you just what COPPUS Blowers can save you in your boiler room. Write for Blower Catalog.

ECONOMY
RENEWABLE
FUSES

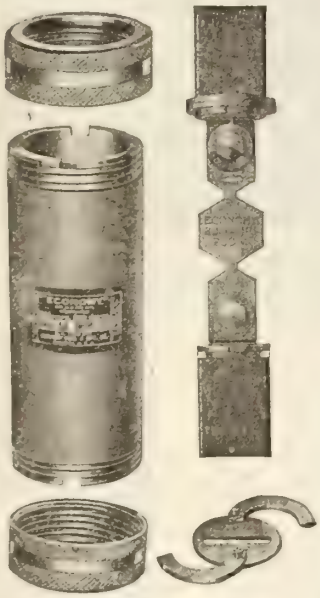
Economy Fuses cut annual fuse maintenance cost 80%.

The only part destroyed when an Economy Fuse blows is the inexpensive strip of fusible metal.

This is almost instantly replaced by a new Economy "Drop Out" Renewal Link. The main portions of the fuse assembly — fibre cartridge — end caps — winged washers — are used again and again.

Dependable protection is obtained by the absolutely accurate rating of the link. Thus does economy and dependability combine to make Economy Fuse Serviceability.

Sold by all leading electrical jobbers and dealers.



Disassembled view knife-blade type showing Economy "Drop Out" Removal Link and Winged Washers.

The Power behind the Wheels of Industry

POWER—mechanical force—harnessed, transmitted and utilized in its most economical phase—is always associated with The Canadian Fairbanks-Morse Co., Limited, whenever the modern oil engine is mentioned.

Wherever boats ply the waters the Fairbanks-Morse C-O engine is found. In the fishing boat the sturdy Type "M" does it duty. A quarter of a million farmers are helping to increase the world's supply of food with the Type "Z". In hundreds of the country's great industrial plants the powerful Fairbanks-Morse Type "Y" is furnishing the power that is speeding up production, keeping down costs, and helping the world of commerce right itself.

Saving time and labor, lowering operation cost, and giving a service that is as near 100% as possible is the record of Fairbanks-Morse engines, for behind each Fairbanks-Morse engine is that 100% quality standard on which the Fairbanks-Morse institution is founded.

Back of every Fairbanks-Morse oil engine is the service of our experts. Avail yourself of this quality and this service. Concentrate your buying and make the Canadian Fairbanks-Morse catalogue your guide.

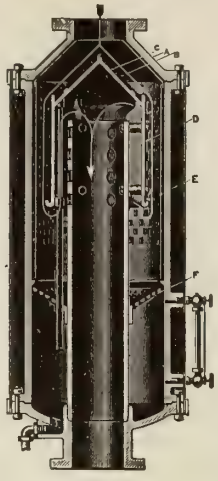
III IMPORTANT THINGS

TO CONSIDER ABOUT A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE — Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION — Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

If It's Rubber—We Make It

In every factory, office, store and household some article of rubber is used daily as an important part of the equipment. Few users recognize its utility or its quality—to them the important item is price.

When you buy rubber goods be certain that you get a Dominion Rubber System Product. It is your assurance of superior quality and satisfactory service. These products include rubber goods for every conceivable purpose, in standard stock sizes, or specially made to meet your needs in factory, mill, mine, lumber-camps, shipbuilding, marine and other industry.

Dominion Rubber System Products

BELTING—Dominion Friction Surface Belting for power transmission prevents practically all power waste.

HOSE—For steam, air, water, oil, acids, fire and every other regular and special purpse.

PACKINGS—Our special packings for high and low compression service, meet every requirement of modern engineering conditions.

FIRE EQUIPMENT—Hose, coats, salvage covers, reels, brass fittings, helmets and every fire fighting requirement.

MOULDED RUBBER—Our lines are particularly complete and include matting, sheeting, floor treads, tiling, gaskets, plumbers' supplies, and moulded and cut goods for every conceivable purpose.

No matter what rubber goods you may need, or what your problem may be, our technical experts can remove all element of doubt and save you many dollars in time and costly experiments.

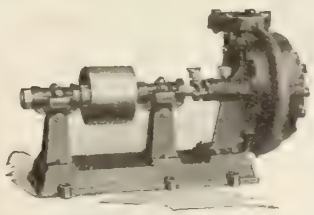
AMERICAN-MARSH PUMPS

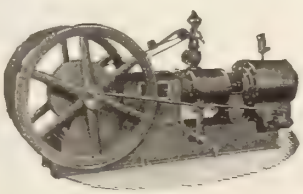
SIMPLE RELIABLE EFFICIENT

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—

Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

Tradition was Disregarded When Goodyear Built Hose

THE beaten path of established customs has rarely been followed by Goodyear scientists.

Rapidly-changing industrial conditions demanded new and more efficient methods.

Breaking away from preconceived ideas of tire-building created the Goodyear Cord Tire—the finest tire in the world.

Applying the same analytical methods to industry, Goodyear redesigned Industrial Hose—scientifically developed it to meet the needs of present-day industry.

Take Goodyear Water Hose as an example.

Water Hose is rarely destroyed through high pressure. But every year thousands of feet is prematurely worn out because the *outside covering* is not sufficient to stand the constant scuffing and pulling over cinders, pieces of iron—against the edges of machines—and so on.

To overcome this, Goodyear Water Hose is built with an extra thick covering of exceptionally tough rubber. A cover which gives greater protection, *longer wear*—lowers costs. And a good inner tube and strong fabric are in keeping with its superior covering.

There is a particular Goodyear hose scientifically designed—as in the case of Goodyear Water Hose—for every Industrial use.

A man trained by Goodyear will be sent to study *your* hose problems—without obligation. Phone, wire, or write the nearest branch.

The Goodyear Tire & Rubber Co. of Canada, Limited

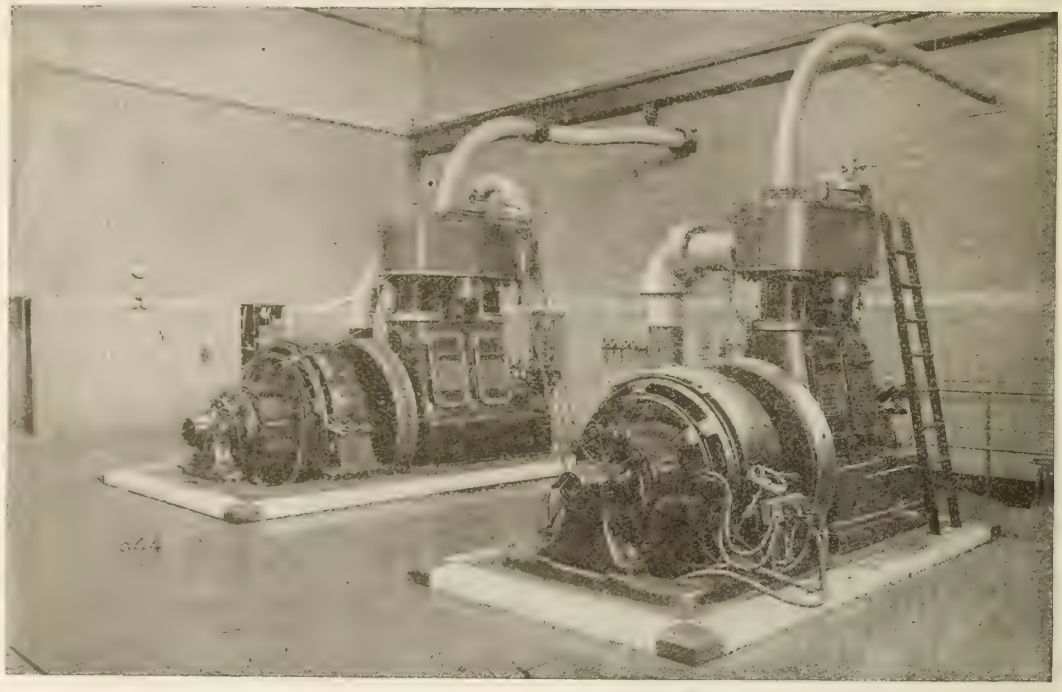
LAURIE & LAMB

"Quality' Power House Equipment



Belliss & Morcom Engines
At McGill University Power House. Total Horse Power, 1010 B.H.P.

What Better Estimation of Worth Than This?

The Belliss & Morcom engines shown in illustration were chosen in preference to other makes by the engineers of the McGill University as best adapted for their power house requirements. This is not the first instance where Belliss & Morcom engines and air compressors have been shown the preference. Their scientific principles and design, and their long-service records are sufficient proof of merit for any practical engineer. That's why you'll find them in many of Canada's most modern engine rooms. When you're in the market do not fail to investigate the Belliss & Morcom line. *Literature on request.*

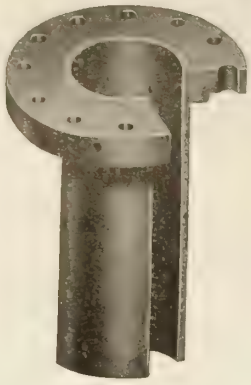
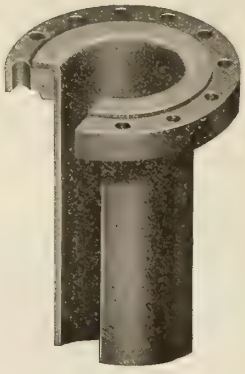
P&H FLANGED PIPE JOINTS



SCREWED



P.H. LAP

P&H LAP FLANGES, for any service, have proven to be the best yet designed, and they have many advantages over other styles. The pipe is not weakened by cutting into the wall as when using screwed flanges. The gasket bears on the face of the lap and absolutely prevents leakage through the bore of the flange. The hub of the flange is bored slightly larger than the outside diameter of the pipe so that the flange will swivel readily and accommodate itself to any slight variation in the position of the bolt holes, an advantage which is obvious to the fitter and eliminates torsional strains in attaching.

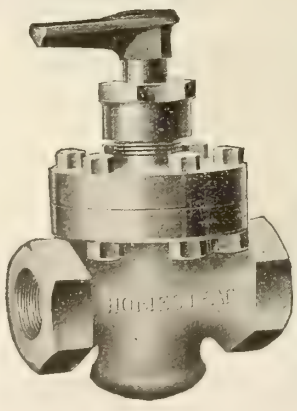
HOMESTEAD
Quarter-Turn Valves

For All Classes of Service



Whenever the duty is exceptionally severe and frequent opening and closing is required insist upon Homestead **Quarter Turn Valves.** They are the "last word" in valve efficiency. A quarter-turn closes Homestead Valves tight — a quarter-turn opens them to a straightway unobstructed flow.

Tightness is absolutely assured by a patented wedging cam that automatically forces the plug downward in closing and instantly releases it again when the handle is turned to open the valve.

Homestead Valves embody the highest quality workmanship and material and will stay tight under any specified pressure up to 5,000 lb. Made in two, three and four way types with semi-steel, brass, or cast steel bodies.

The Homestead Way is the only way. Investigate!

A Continent-Wide Service

Not Primarily a Fuel Saver, Yet It Has a Top-Notch Record for B.T.U.s Saved.

We are extremely conservative when stating the fuel-saving ability of the Dunham Radiator Trap.

In home heating systems, the methods of firing vary so, that we positively refuse to make any definite claims regarding economy. But large installations form a different story—and one which you will find most interesting. May we tell it to you?—that you may see just where the Dunham Radiator Trap fits into your fuel-saving scheme.

"The Dunham Hand Book" is full of facts. Send for your copy.

YARWAY
Pipe-Joint
Clamp

Description.—1. Split ... 2. ... screws 4. 3. Outside ring, bolted around pipe by bolts 6, secured by ... adjusting screws 4.

The Best Insurance Against Leak Losses

With a Yarway Pipe Clamp, one workman can stop most any steam-line leak, large or small—stop it permanently and in less than ten minutes.

Any leak in your steam lines, whatever its size, is a serious matter with coal at its present prices. Yet the cost of a shut-down to replace the damaged section of pipe is even more serious.

Perhaps, in order not to interfere with production, you are overlooking the leaks—and paying the increased coal bills. But if you could have these leaks completely and permanently repaired in a few minutes, with no interference to work, wouldn't you rather save your coal?

YARWAY

Pipe Clamps

The Yarway Pipe-Joint Clamp stops leaky joints. The Yarway Holtite Pipe Clamp stops holes and splits in straight pipe. Both are stocked in all the usual sizes for immediate shipment.

A supply of Yarway Pipe Clamps on hand is the best possible insurance against leak losses. We'll be glad to send you one to test, without obligation. Write for Bulletin No. C-805, and see what users say about them.

Yarnall-Waring Company

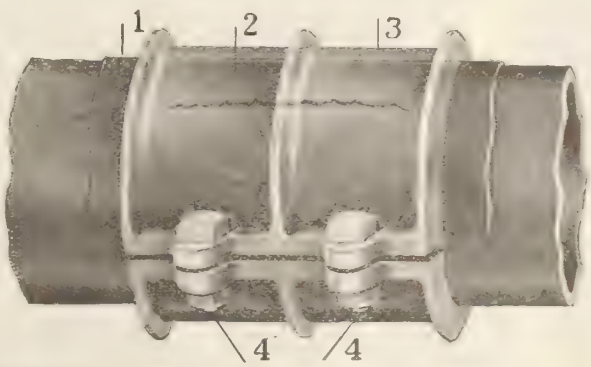
Carried in stock by dealers in thirty principal cities



Yarway Holtite Pipe Clamp

Packing (1) is placed over hole or split (2) in pipe; metal clamp (3) is then placed over packing and around pipe; bolts (4) tighten clamp and hold it in place.

Every Boiler—Whether Fired by Coal, Pulverized Fuel, Oil, Waste Heat, Natural Gas, Bagasse or Refuse—To Operate Economically Must Be Cleaned at Frequent, Regular Intervals.

Every type and grade of fuel produces soot. When certain kinds of fuel are used under favorable conditions of combustion, the deposit is less than at other times. But under no circumstances is the deposit of insulating matter ever so small as to warrant the omission of frequent, regular cleaning.

As an illustration, it would be hard to find a cleaner fuel than natural gas. Yet one of the country's large central stations which uses natural gas at certain seasons of the year, recently found that, due to its failure to operate its mechanical soot blowers regularly after the Spring switch from coal to gas, its flue gas temperatures were 200° higher than they should have been. By using the soot blowers once or twice in 24 hours, they kept the boilers clean—reduced flue gas temperatures—saved fuel—and increased boiler efficiency and capacity.

When it comes to boilers fired by blast furnace gas and waste heat from open hearth or reverberatory furnaces, the gases are so loaded with foreign material that boiler capacity and efficiency can only be maintained by the use—four to six times a day—of mechanical soot blowers.

What is true of gas-firing is doubly true of oil and coal firing. You can not get proper heat transference through soot and ash covered surfaces. Diamond Soot Blowers are a necessary part of every steam boiler and every economizer.

Write for full information, requesting your copy of Bulletin 280.

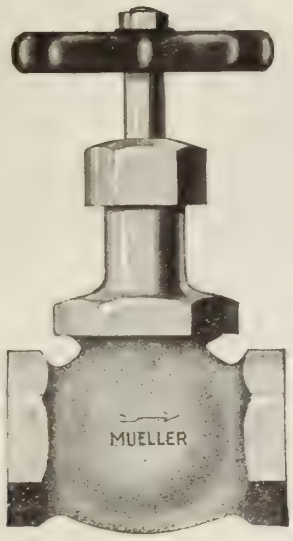
MUELLER
BRASS GLOBE VALVES



Registration Numbers:

Province of Ontario No. 1780
for 175 lbs. pressure.

Province of Alberta No. 1116
fo 150 lbs. pressure.

MUELLER Brass Globe Valves are recommended for a working pressure of 125 lbs. The special features appended justified voluntary registration for working pressures of 175 lbs. and 150 lbs. by the Chief Boiler Inspectors of Ontario and Alberta respectively:

DESIGN
Special barrel shaped body. Female thread on bonnet.

METAL
High copper and tin content giving a tough, close grained casting with pressure resisting qualities.

PACKING
Special packing composed of asbestos and graphite with lead core wire to resist high pressure.

MUELLER Globe Valves are being substituted for competitive patterns of composition disc Valves.

For low pressure service ideal results are secured by the use of the Empire Steam Trap. It is the result of 35 years' experience in the manufacture of steam traps. The inverted valve seat absolutely prevents any sediment lodging on seat, and causing the trap to blow or leak. The blow-off plug is located directly under the valve seat. Float is of guaranteed seamless electro-plated copper, tested to 150 pounds pressure. The automatic air valve operates by expansion. It is placed on the highest point in cover of trap, thereby preventing the formation of an air pocket. There are two inlets, and one outlet, making it convenient to pipe; it is particularly adapted to working where there is slight head room.

The Simplex Condensation Meter gives an accurate record of the flow of condensate or other liquid, where there is a gravity discharge. Its measuring chambers are controlled by an automatic oscillating arm, which combines simplicity of operation with accuracy of measurement. It is practically noiseless in operation and requires no attention. Its construction is strong and substantial, with all parts carefully machined.

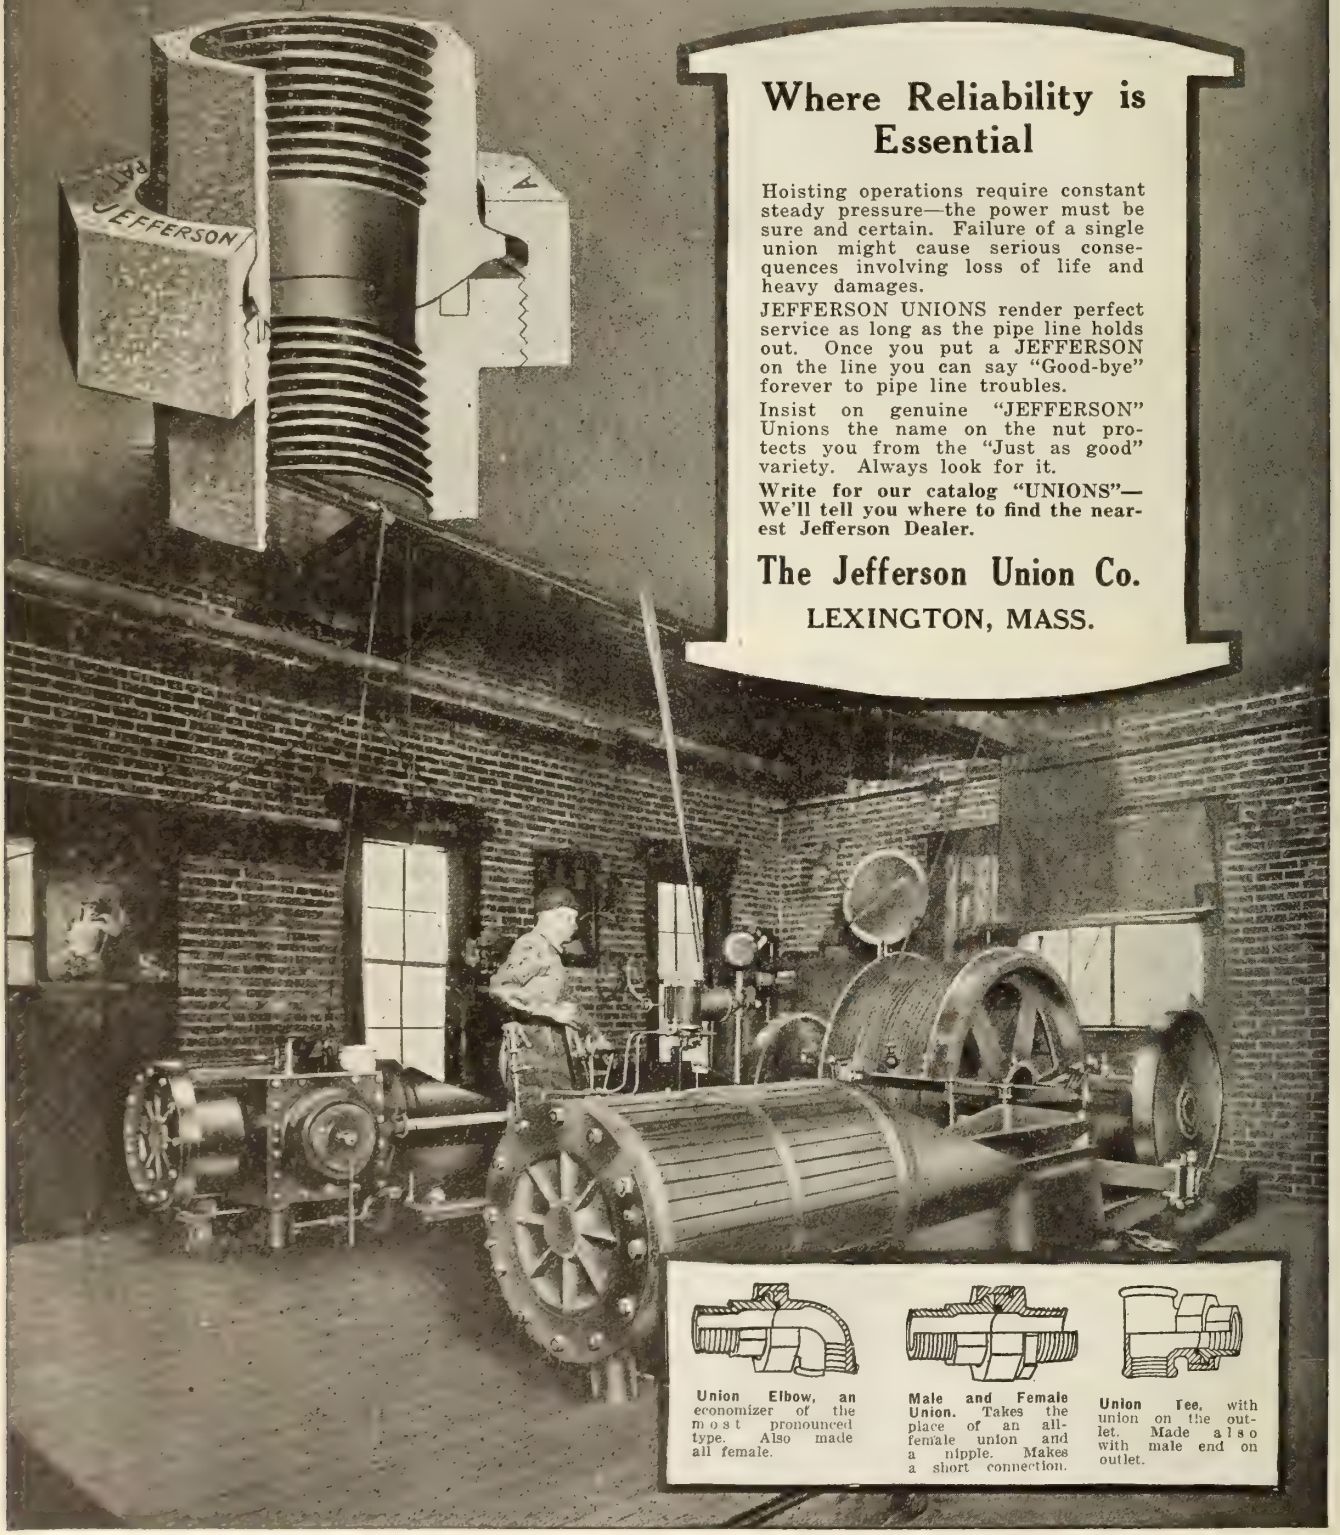
JEFFERSON

"Look for the Name on the Nut"



Where Reliability is Essential

Hoisting operations require constant steady pressure—the power must be sure and certain. Failure of a single union might cause serious consequences involving loss of life and heavy damages.

JEFFERSON UNIONS render perfect service as long as the pipe line holds out. Once you put a JEFFERSON on the line you can say "Good-bye" forever to pipe line troubles.

Insist on genuine "JEFFERSON" Unions the name on the nut protects you from the "Just as good" variety. Always look for it.

Write for our catalog "UNIONS"—We'll tell you where to find the nearest Jefferson Dealer.

The Jefferson Union Co.

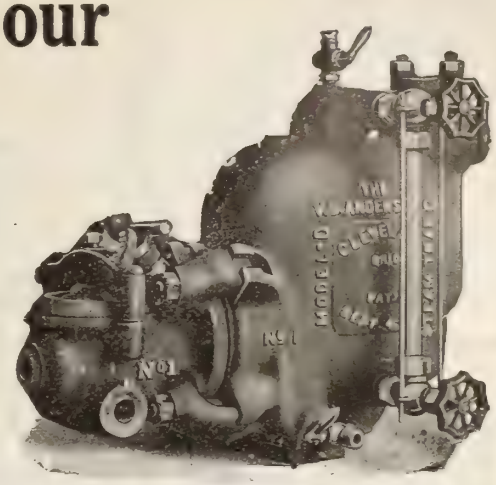
LEXINGTON, MASS.

Union Elbow, an economizer of the most pronounced type. Also made all female.

Male and Female Union. Takes the place of an all-female union and a nipple. Makes a short connection.

Union Tee, with union on the outlet. Made also with male end on outlet.

Leaky Traps Increase Your Operating Expenses



How much steam are you wasting by allowing it to escape into the air or the sewer, past poor steam traps?

Stop this needless increase in your operating expenses by installing

ANDERSON
Model "D" Steam Traps

They are designed to give long, tight service. The deep water seal prevents the escape of steam. Operated by a simple counter-balanced float mechanism that can not get out of order.

All dirt and sediment is caught in the self-contained removable strainer and cannot enter the trap. An outside gauge glass shows how quickly the trap is filling and discharging.

They'll quickly pay for themselves by keeping your pipe lines free from condensate **without steam loss.** Write for descriptive catalog.

Insure Constant Level

The most economic way to operate boilers is with constant water level and uniform constant inflow. With the level held constant at middle gauge the greatest amount of heating surface is presented to the hot gases and the maximum amount of steam space is available.

Vigilant Feed Water Regulators

meet these conditions in a very satisfactory way.
They are easily adjusted to maintain an absolutely constant water level at any arbitrarily determined height in boilers and they feed continuously with perfect uniformity.

Write for full particulars.

DEPARTMENT OF LABOUR
Ontario Government

Minister: Hon W. R. Rollo — **Deputy Minister: W. A. Riddell, Ph.D.**

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a **Stationary** steam plant of 50 B.H.P. or over, and everyone operating a **Hoisting** steam plant working at a pressure of 20 pounds or over, irrespective of horsepower and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a certificate from the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

All applications should be mailed to the Chairman of the Board. W. C. McGhie, Department of Labour, 15 Queen's Park, Toronto.

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering, the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., ch. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, 15 Queen's Park, Toronto. D. M. Medcalf, Chief Inspector of Steam Boilers.

The Hays Automatic CO_2 and Draft Recorder (Patented)

Tells Exactly Why Too Much Fuel is Consumed

With these appliances installed, your firemen can fire intelligently; instead of groping in the dark they will work with accurate facts before them. For the Hays CO^2 and Draft Recorder permanently records the story of your combustion efficiency.

Even the most modern power plant may waste 25% of its coal unless proper steps are taken to correct errors in firing, draft, boiler settings, etc.

Modern equipment is just as efficient as its operation allows. Accurate facts of your combusion and the knowledge to apply these facts are necessary—

The Hays CO^2 and Draft Recorder, supplies the facts and the Hays Book—"How to Build Up Furnace Efficiency"—helps you interpret and apply them. This interesting book is in no sense a catalog—and it has gone through fourteen editions.

The coal shortage is becoming more acute.

As the first step towards securing better results with less fuel—investigate Hays Apparatus.

Hays Gas Analyzer
1919 Model
Patent No. 1,077,342

The Jos. W. Hays Corporation

MICHIGAN CITY INDIANA, U.S.A.

Class N-SBE Motor-driven Compressor installed by Taylor & Dean, Pittsburgh, Pa. Capacity 147 cubic feet per minute.

An ideal unit for moderate air power needs

CHICAGO Pneumatic Short-Belt Motor-Driven Air Compressors are ideal units for the small air power plant. Their compact construction economizes space. The short-belt drive with idler pulley prevents belt troubles

These units embody the same advanced principles of design and construction as the larger Chicago Pneumatics—Simplate Indestructible Flat Disc Valves, automatic regulation and lubrication, great rigidity, liberal bearing surfaces—all insuring more power with less waste; longer service with less upkeep.

Electric motor, steam and belt-driven types of these units are usually available from stock at the Company's branches listed below. Capacities 69 to 1197 cubic feet per minute.

BOILER ROOM ECONOMICS—

have assumed an importance unthought of in the past. Due to the scarcity of coal and a poorer quality of what can be obtained; and also to increased costs in every item of boiler and furnace operation and maintenance, only the best operating conditions are economically permissible to-day.

THE BERNITZ METHOD—

of furnace wall construction offers many distinct advantages over the old method of furnace lining, owing to the complete elimination of clinker formations on the brick work and a reduction of clinkers in the fire bed.

It will pay every user of coal to investigate the possibilities of this method of furnace wall construction. We have an interesting booklet describing it which we would like to send you.

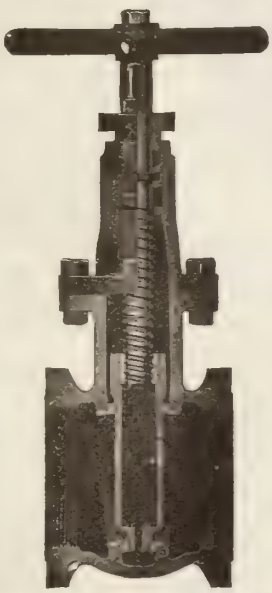
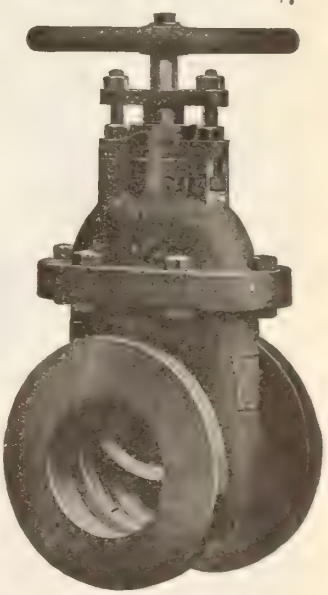
KERR

("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.



If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.



When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

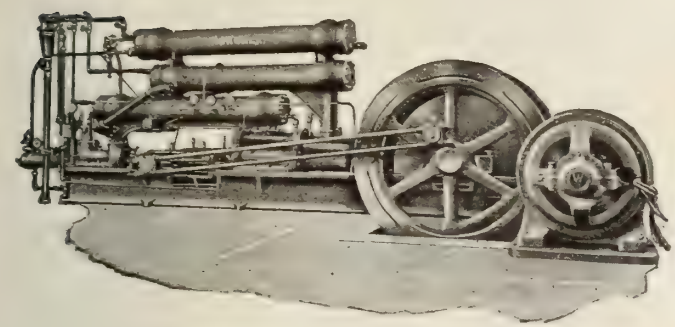
NORWALK
AIR & GAS · COMPRESSORS

There IS a Way to Be Sure



Norwalk 24-in. Stroke Chain-Driven
Four-Stage Air Compressor

There is never any guesswork concerning the results you will get from a Norwalk compressor. Our engineers study your operating requirements, your source of power, and all other installation details, before making a recommendation. When they do make it—**it's right.**

Whatever your compressing needs may be, the way to be sure of meeting them fully, lastingly and with economy is to select the Norwalk.

Norwalk bulletins on compressors for air, oxygen, hydrogen, carbonic acid gas or acetylene contain the information you are looking for. Write for the ones which interest you.

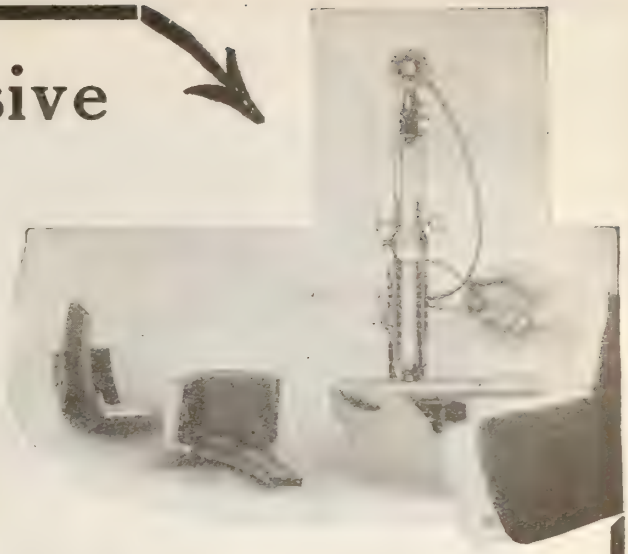
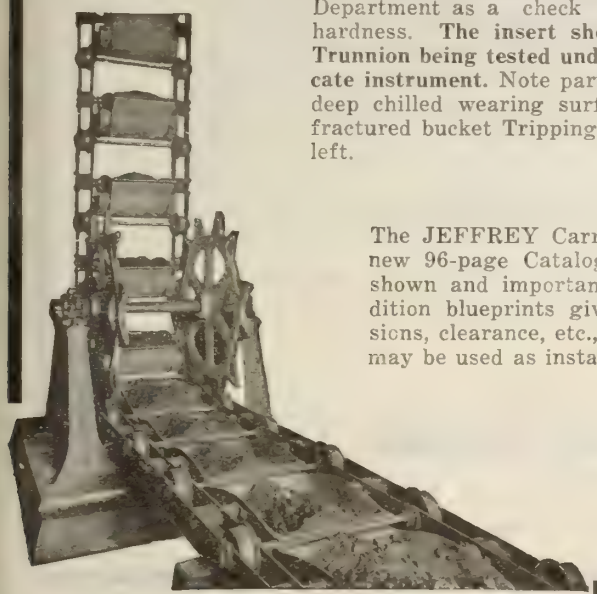
The Test is Conclusive

The extreme hardness of all wearing parts in the

Jeffrey Carrier



is proved conclusively by this test. The Scleroscope is used by our Inspection Department as a check for proper hardness. **The insert shows a Steel Trunnion being tested under that delicate instrument.** Note particularly the deep chilled wearing surfaces in the fractured bucket Tripping Cam to the left.



The JEFFREY Carrier is completely described in our new 96-page Catalog. Interesting shop views are shown and important installations illustrated. In addition blueprints giving all necessary general dimensions, clearance, etc., are included in the Catalogue and may be used as installation drawings.

Write TO-DAY for your copy of our new Catalog. Ask for No. 210—4. You'll find it valuable in making layouts for Coal and Ash Handling Installations.

MONTREAL: Southam Bldg. LONDON, ENG.: 88 Fleet St., E.C. WINNIPEG: 1103 Union Trust Bldg.

Vol. XIII.—No. 14. Publication Office, Toronto—July 20, 1920 Published Semi-Monthly Canada, $2; U.S. $2.50 a year

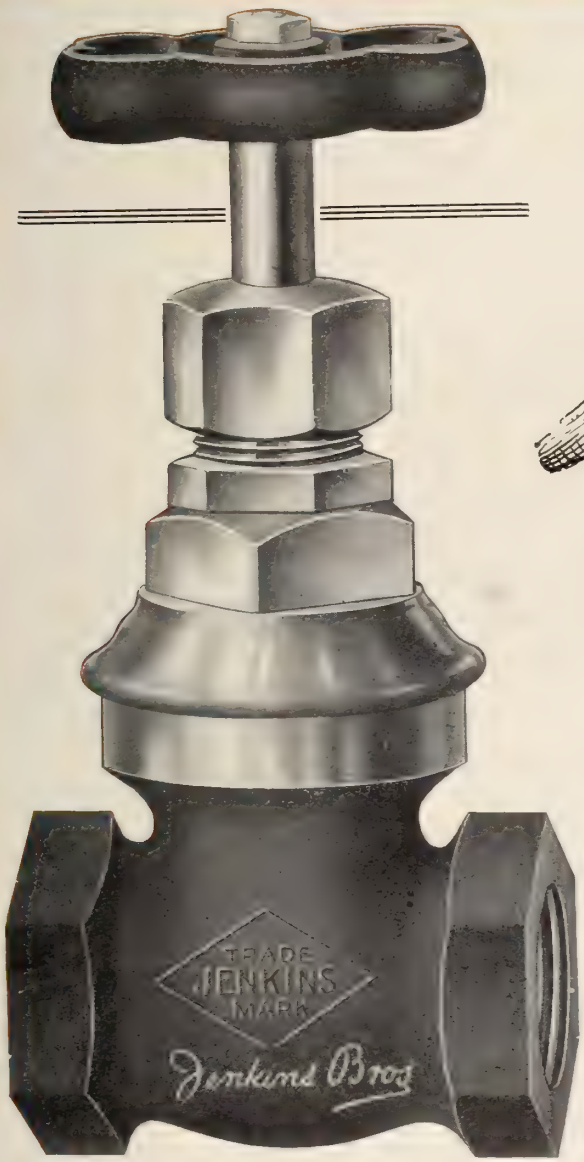

Fig. 300
Type "K" Brass Gate Valve
Screwed

It Will Stand The Test No Matter How Severe

Long and satisfactory service under the most trying conditions of usage, elimination of re-installation costs and replacement charges, upkeep expenses reduced to the very lowest minimum—these are the points by which to determine true valve value.

The type K gate valve illustrated herewith is one of the most popular of the Jenkins' line, and it will pay you to investigate its merits if entirely trouble-free service is a consideration.

First-class dealers everywhere stock genuine Jenkins Valves. Write for copy of Catalog No. 8 and see how complete the Jenkins line is—a valve for every purpose where a valve is required.

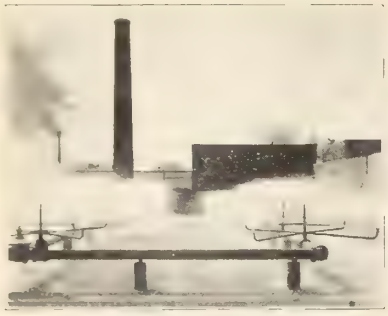
"SPRA-RITE"

Cooling Systems for Cooling Condenser Water



Iowa Railway & Light Co., Marshalltown.

Central Illinois Public Service Co., Harrisburg, Ill. Capacity 10,000 G.P.M.

A System of Growing Importance

Owing to the rapid adoption of the Steam Turbine and Steam Condensation Equipment water cooling has become a factor of great importance to the manufacturer.

Whitman & Barnes Mfg. Co., West Pulman, Ill.

For this reason plant sites within easy reach of natural bodies of water for condensation are in demand. But such sites are not always available. It is then necessary to install Spray Cooling Ponds for cooling the condenser water so that the available supply can be used over and over again.

Cooling systems representative of the best practice a decade ago are virtually obsolete now. "The SPRA-RITE" System fills the bill to-day, meeting as it does all the requirements in the shape of capacity, flexibility and cooling efficiency.

Spray ponds can be in any shape, depending upon the space available. Concrete ponds are extensively used; this is conceded to be the best practice. Natural ponds and specially constructed earthen basins may also be used with success. If ground space is limited a building roof may be utilized.

We furnish plans and recommendation for any kind of installation.

A Safe and Profitable Investment

Spray Cooling Ponds, when equipped with our well-known SPRA-RITE Nozzles and Cluster Fittings are giving such remarkable cooling capacity that it has led to their adoption by the largest Power and Industrial Plants of this and other countries.

Tests made on the coal pile by means of the increased vacuum obtained prove that many systems have made a 50 to 100 per cent. return on the original investment in a year's time. Frequently a reduction in insurance rates are also obtained by reason of ample water supply close at hand for use by fire pumps.

SPRA-RITE Cooling Systems have proved their efficiency for ice plant service. They are now considered standard equipment by refrigerating engineers, and ice plant operators.

For Steam Condensing equipment SPRA-RITE Cooling Systems represent the highest standard of efficiency, but a spray cooling system will show its highest efficiency only when equipped with SPRA-RITE Nozzles, which were primarily designed for this application.

Your inquiries involving the cooling of water are invited.

SPRA-RITE Two-Vane Nozzle—its function is to discharge fine spray of equal density throughout their entire cross section.

The Supreme Test—Service

THERE is only one test for a lubricant and that is "service"—service rendered under service conditions. The full benefit from capital sunk in expensive machinery can only be reaped through *correct* lubrication—*the best lubricants properly applied.*

Imperial Lubricants need no introduction. They are known and used from coast to coast. They are graded for every type of machine; are Canadian made from the finest crudes and readily obtainable in all parts of the Dominion.

Choose your lubricants from the Imperial line. Take advantage of our offer of free consultation. Both aim to assist you to insure that production shall bear a true relation to the time, thought and money expended in equipment.

Correct lubrication means the selection and proper application of the right lubricant for each machine. Correct lubrication actually promotes maximum profits, increasing production per unit and decreasing depreciation charges, fuel and repair bills.

Imperial Lubrication Engineers are at your service for consultation in solving troublesome lubrication problems. Their advice is free. Write to us at 56 Church St., Toronto, or to any of our branches.

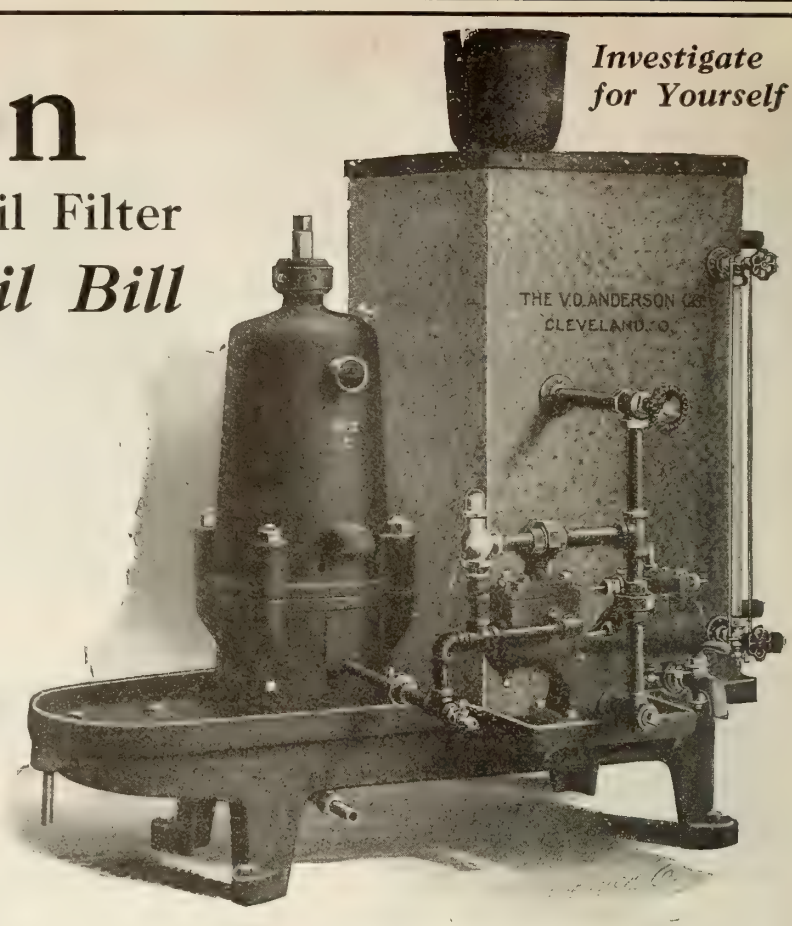
The **Anderson**

Pressure Oil Filter

Will Cut Your Oil Bill in Half ——

Investigate for Yourself



It is a fact by collecting the waste oil in drip pans, properly located beneath the engine or machinery; and running it through the Anderson Filter you can actually save at least one half of your oil bills. With the Anderson Filter the used oil undergoes a cleansing, purifying treatment identical to that of the refiners. It comes from the Filter clean and pure, suitable for use on the finest bearings.

Look up your yearly consumption figures; consider the ever increasing prices of oil and the fact that you can save at least one half on every oil bill. Then write for the Anderson catalogue and prices. This is an economy of too great importance for you to overlook. Write to-day.

Giant oil engines pay for themselves

GIANT Oil Engines cut down monthly power bills sufficient in most cases to return their initial cost within a short time.

The cost of oil for fuel is low. Giant Oil Engines burn most efficiently the lower grades of low-cost fuel oil.

Through automatic regulation they prevent waste of fuel and power and eliminate the human factor in obtaining power efficiency.

Their sturdy, simple construction—free from valves, magnetos, carburetors, wiring and other complicated devices—prevents breakdowns and the expense of frequent replacements.

Power costs of ½ to ¾ cent per horse power hour are common amongst Giant Oil Engine users.

Performance records are available showing the dependability and operating economy of Giant Oil Engines under service conditions similar to yours.

Ask for bulletin.

Giant Semi-Diesel Oil Engines are built in capacities from 12 to 200 H. P., both single and duplex types. They embody such important features as box-type crosshead construction, hot liner ignition, and totally enclosed frame and automatic lubrication.

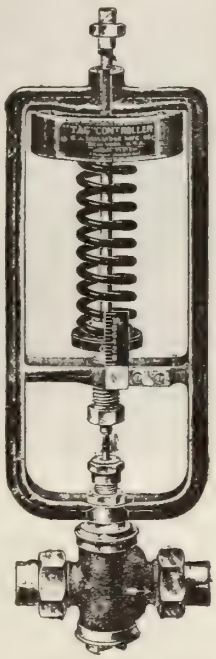
Dependable Power at *Less Cost Per Hour*

No Overtime For Night Work

Any machine operated by power, works best and most economically at a certain definite pressure.

This pressure cannot be regulated by a hand valve, because a hand valve is not suitable—it's too uncertain.

A TAG Self-Operating Pressure Controller on the supply line, will maintain the desired pressure night and day, as long as the power is on.



It needs no care and attention. It is absolutely automatic. You merely set it and leave it alone. You can go away and forget it.

It differs from human labor, in working just as well when the foreman is absent, as it does under the foreman's eye. It works over-time all night, if necessary—without protest, without over-time pay.

In fact, it pays its own wages by reducing direct labor cost and by economy of power and fuel.

No Stoker is Better Than its GRATES

MURPHY AUTOMATIC FURNACES

Back of every feature of MURPHY GRATE construction are *many* sound reasons. Consider how these features save you dollars—in fuel—in labor—in maintenance.

The long—narrow—but deep sections give eighteen to twenty-eight square inches of cooling surface to every inch of exposed grate surface.

The liberal air space (47% to 52%) gives double the capacity of the boiler "without one penny for draft."

The correct proportion and distribution of ribs on the stationary grates, combined with the greatest accuracy of machine moulding have solved the sifting problem. The continuous movement of the ribless grates 3/4" above and 3/4" below the surface of the stationary grates—breaks up the fuel bed—prevents avalanching—keeps the grates clinker-free—and advances the ash gradually to a point where it is removed by the clinker grinder. It is this action that gives the Murphy Furnace the faculty of ***burning anything that has heat in it.***

Yet with all these advantages, the Murphy Grate of to-day is built to the same policy that has characterized every improvement First, to make all parts standard; second, to make every piece interchangeable; third, to advise users of new developments so that they may keep their equipment up to date—and operating at top notch efficiency.

For information on the Riley Underfeed Stokers for large boilers, see February 5 advertisement or send for Riley Stoker catalog HR-6.

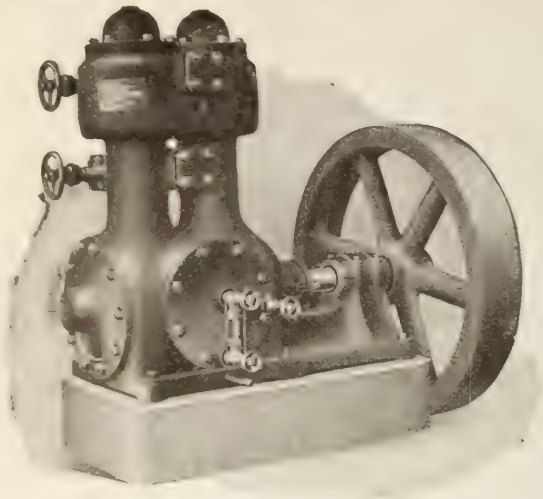
Mechanical Refrigeration



Reliable--Beneficial

THE many benefits common to all users of MECHANICAL REFRIGERATION, should make it a valuable adjunct to **your** business.

The uniform temperatures it provides have a better holding effect on the product in storage than ice, because the temperature produced by ice is not uniform, varying with the amount of ice in the refrigerator.

MECHANICAL REFRIGERATION permits the maintenance at all times of any temperature desired in the refrigerators or cold storage rooms, whereas you can not always get ice just when you need it, and a delay of a few hours often means a loss through deterioration of the product in storage.

If interested in MECHANICAL REFRIGERATION, a request for information and prices will receive our prompt attention.

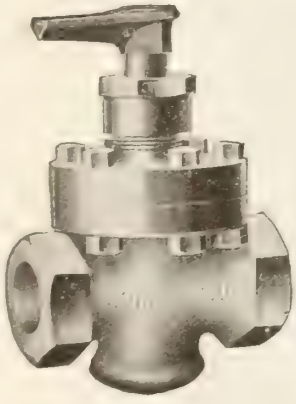
HOMESTEAD

Quarter-Turn Valves

For All Classes of Service



Whenever the duty is exceptionally severe and frequent opening and closing is required insist upon Homestead **Quarter Turn Valves.** They are the "last word" in valve efficiency. A quarter-turn closes Homestead Valves tight — a quarter-turn opens them to a straight-way unobstructed flow.

Tightness is absolutely assured by a patented wedging cam that automatically forces the plug downward in closing and instantly releases it again when the handle is turned to open the valve.

Homestead Valves embody the highest quality workmanship and material and will stay tight under any specified pressure up to 5,000 lbs. Made in two, three and four way types with semi-steel, brass, or cast steel bodies.

The Homestead Way is the only way. Investigate!

ALL-WAY

Flexible Spout Grease and Oil Guns

Make it easy to refill the most out-of-the-way gear cases or transmission as the flexible spout can be bent to any desired angle. The Cleaning Device at the end of the **"ALL-WAY"** spout reduces cleaning time and oil wastage to a minimum. The **"ALL-WAY"** gun is especially useful and handy in filling lineshaft hanger reservoirs.

If your dealer cannot supply you, write us.

We also manufacture the well-known "ALL-WAY" Oil Can. Saves you 50% of your oil bill.

Dominion Belting Company, Limited
Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.

"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

World-Wide Demand for Goodyear's Quality of Belting and Hose Makes Advisable Some Changes in Brand Names

Example—GOODYEAR { *formerly*—"Extra Power" / *now* —"Klingtite"

THE most widely known belting in Canada to-day is "Extra Power."

Now you will buy this same belting as Goodyear Klingtite belting —"Klingtite"—a name adaptable to world-wide use.

In our sales messages you will read of Goodyear Klingtite instead of Goodyear Extra Power.

Our Belting men will talk to you of Goodyear Klingtite instead of "Extra Power."

The familiar brand names of Goodyear belting, hose and packing have been changed so that each of these products may be called by the same name in Australia, Europe, South Africa, India, Japan, China and other countries, as in Canada.

The new brand names are such that they can be used and understood in practically every language and country without change.

Some of the former names designed and reserved for Canadian use do not lend themselves to the complication of languages and conditions prevailing in some of these foreign countries.

Goodyear Belting, Hose and Packing, made in Canada, have become products of world-wide sales.

You will welcome the development of this phase of our business because it means the building up in Canada of another world-wide manufactory. It means increased demand and prosperity for Canadian workers. It means economy and service for you.

Particularly to you, it means that efficient engineers and factory superintendents the world over endorse your choice when you secure belting, hose and packing for your plant.

Phone, wire or write the nearest Goodyear branch for a man trained by Goodyear in belting, hose and packing problems to call on you. No obligation.

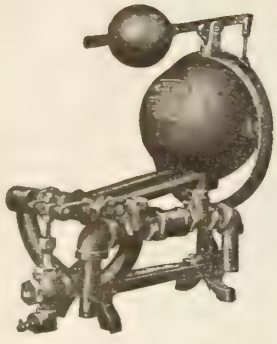
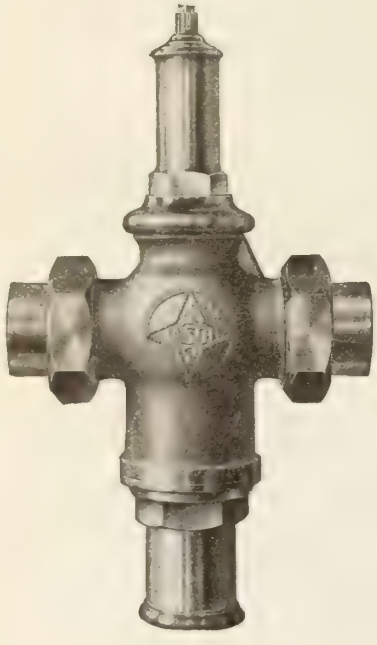
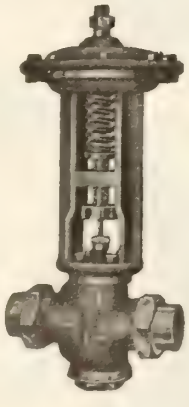
Mason Power Plant Equipment

QUALITY

SERVICE *RELIABILITY*







The splendid reputation of MASON POWER PLANT EQUIPMENT is not the result of an accident, but the expected outcome of thirty years of persistent effort backed by large capital and superior manufacturing facilities.

They hold the FIRST place to-day because their merits entitle them to that position.

No other devices work so accurately, wear so long, nor accomplish their purpose so fully as the MASON. Once installed they are always demanded thereafter, and thousands of manufacturers absolutely depend on these devices working in many critical locations and find them satisfactory.

MASON equipment includes the following well-known lines:

Mason Reducing Valves
Mason Pump Pressure Regulators
Mason Balanced Valves
Mason Strainers
Bundy Steam Traps
Bundy Oil Separators
Stratton Steam Separators
Reilly Feed-water Heaters
Reilly Evaporators
Reilly Distillers
Reilly Feed-water Filters
Republic Flow-meters
and other high-grade devices.

Automatic Cleaning Stoker

Save Coal!

—your Duty to Canada and Yourself

OF THE seven million tons of coal used last year by leading Canadian industries and public utility plants, one million tons could have been saved by the application of scientific methods of combustion.

1,000,000 tons of coal saved in Canada in one year!

20,000 coal cars released for other service!

Your Part

in Eliminating Canada's Annual Coal Waste of a Million Tons

What is your share of Canada's excessive coal bill? One seventh of the coal consumed by industrial Canada in 1919 could have been saved.

As a Canadian power user—a part of Canada's industrial backing—you owe it to the nation to assist in abolishing this preventable waste.

And as an engineer, plant owner, or director you owe it to yourself and your organization to save every pound of fuel that can be saved—particularly so to-day, with coal prices going constantly higher and the supply of coal inadequate to meet domestic demand.

Twenty million tons of coal were imported from the United States in 1919. This could have been reduced to nineteen million.

Canada's preventable fuel waste is, of course, largely the result of improper stoking.

And since hand firing is the commonest form—although by no means the only form of improper stoking—this abnormal fuel bill is largely traceable to hand firing.

Is your plant hand fired? Is it incorrectly stoker fired?

No other single step you can take could possibly rival the importance of installing the right kind of stoker in your plant—if you have Canada's interests and your own interests at heart.

The announcement on the opposite page will be of vital interest to Canadian power users:

Pays for

Itself

This Greatly Expanded Engineering Organization Will Help You

The Jones Under-Feed Stoker Company, Limited, has been reorganized, and its name changed to the Under-Feed Stoker Company of Canada, Limited. The following are the officers and directors of the Company:

President: Lloyd Harris, late Chairman of the Canadian Trade Mission, London, England; President Russell Motor Car Ltd.; President the Under-Feed Stoker Company of America.

Vice-President and General Manager: S. A. Armstrong, Vice-President and Managing Director of the Under-Feed Stoker Company of America.

Vice-President and Secretary: James L. Ross, Barrister, etc., Secretary of the Under-Feed Stoker Company of America.

Directors: T. A. Russell, President Willys-Overland Ltd.; Vice-President Russell Motor Car Ltd., and Director of the Under-Feed Stoker Company of America.

A. E. Holmested, Barrister, etc., and Director of the Under-Feed Stoker Company of America,

H. J. Fuller, President Canadian Fairbanks-Morse Company, Ltd.

David Fasken, K.C., President Excelsior Life Insurance Company.

This Directorate and reorganization makes available for all industrial Canada the engineering experience and development of mechanical stokers of The Under-Feed Stoker Company of America, and The Under-Feed Stoker Company of Canada, Ltd.

This Canadian Company has carried on business in Canada for the past twenty years. Its stoker equipment is manufactured in Canada, is sold for Canadian money at par.

This is the oniy stoker company doing business in Canada to-day that is qualified from the standpoint of equipment to handle any type of combustion problem presented.

Jones Stokers vary in size and type from what is known as the Jones Standard Stoker, manually cleaned, to the heavy duty "A-C" Stoker for the largest type of power plant and boilers.

Standard Stokers may be furnished with side cleaning astachments, eliminating the manual training methods. A heavy-duty side cleaning stoker is also furnished fo. boilers from 250 h. p. to 500 h.p. rating.

Getting Down to Figures

THESE comparative figures show how the Canadian manufacturer can conserve coal and make money for himself by equipping his plant with Jones Stokers.

Boiler Plant consisting of Six 250 h.p. Boilers:

Assuming 5 boilers operated for 24 hours a day, 300 days a year, 1 boiler held in reserve:

Two shifts of 12 hours—
Labor at 50c an hour
Coal at $6.00 a ton

Cost of installation of Jones Stokers, $17,000.00.

Annual Cost of Hand Firing

Labor: 5 men per shift . .	$18,000.00
Coal: 4½ tons per B.H.P.	121,500.00
	$139,500.00

Annual Cost of Stoker Firing

Labor: 3 men per shift. .	$ 10,800.00
Coal: 12% saving.	106,900.00
Depreciation: 10%.	1,700.00
Repairs: 5%.	850.00
	$120,250.00

Capacity of Plant increased from 50% to 100%.

Additional saving made possible through burning of cheaper grades of coal.

Annual Saving—Stoker Firing over Hand Firing. . $19,250.00
Return on Investment . . . . . 113 per cent.

With the engineering service of this company at the disposal of the Canadian manufacturer, can he hesitate for one moment to call for assistance in solving his combustion problems?

WAIT STEAM TURBINES

The Acme of Perfection

MANY recent improvements in detail by skilled investigators have resulted in the G. & McC. Co. "Wait" Steam Turbine reaching a high point in efficiency—it is in fact recognized by leading engineers as the acme of perfection in steam turbines. Some of its leading features include in addition to high efficiency—simplicity, ruggedness and economy of operation.

Points of this ***G. & McC. Co.*** *Machine that should be remembered are:*

—The Turbine is entirely automatic.
—No oil or grease cups.
—Stuffing boxes and glands, seldom require attention.
—Emergency governor and valve are entirely separate from main governor and valve.
—Interior may be easily inspected.
—Self-lubricating; dust proof; dirt-proof.
—Speed can be changed while running.
—LOW RUNNING EXPENSE AND COST.

Air Pumps for Condensing Equipment

In This Paper Read Before the American Society of Mechanical Engineers, the Writer Discusses Past and Present Types—The Leading Features Are Described, with Special Attention to the Steamjet Ejector.

By FRANK R. WHEELER

THE past few years have brought about decided changes in three component parts of a steam power plant:

(a) The steam turbine has replaced prime movers of the reciprocating type;

(b) Mechanical stokers of fuel have increased boiler efficiency and ratings;

(c) Improved condensing equipment is now used which will maintain vacua of 29.5 in. referred to a 30-in. barometer under operating conditions and with proper water temperatures.

The improvement in condensing equipment is primarily due to the better designs of air pumps adopted and to the radical changes and innovations that have been introduced since 1914, and the following review, dealing with past and current practice in air-pump design and selection, is submitted in the hope that it will prove of interest.

Classification of Air Pumps

2. Air pumps may be classified as follows:

- Displacement
  - Wet-vacuum pumps, handling liquid and vapor
    - Simple, 3 valve decks
    - Edwards
    - Rotrex
    - Mullan
  - Dry-vacuum pumps
    - Simple
    - Two-stage
- Impulse
  - Rotary
    - Leblanc
    - A.E.G.
    - Roturbo
    - Thyssen
    - Weir
  - Ejectors
    - Water
      - Koerting
      - Kinetic
      - Muller
    - Steam
      - Radojet
      - Evacter
      - Leblanc
      - Briguet
      - Occluder

As most of these types are well-known to engineers, but little attention will be given to the older designs.

Wet-Vacuum Displacement Pumps

3. "Wet"-air pumps have proven their merit for more purposes and duties than is often realized, and are to-day to be recommended and installed with a clear conscience. For a simple power station or a small unit up to, say, 2,000 kw. capacity the question of style and trend has often influenced the selection of a more complicated system. Improvements have been made in the better-known pumps of this class so that volumetric efficiencies have been materially improved and power consumption reduced.

4. Succeeding the original bucket-type pump with three valve decks, the Edwards air pump, the principle of which was described in 1845* by Bodmer, was introduced into this country in 1900 by Mr. C. H. Wheeler, and is in general the best-known pump with wet-vacuum type. It is a vertical-piston displacement pump with suction ports in the cylinder wall which are uncovered by the piston at the bottom of the stroke, a vacuum being produced in the cylinder barrel by the downward movement of the piston. Upon the suction ports being uncovered by the piston the pressure in the cylinder barrel and the condenser is equalized, the condensate entering the pump with the vapors. The upward movement of the piston closes the ports and compresses the entrained air and vapors to atmospheric or discharge pressure and discharges the mixture through valves in the head.

5. The horizontal suction valveless pump had also been developed, and in this country as the Bailey pump preceded the designs of Blake, Knowles, and Mullan. These pumps and the later improved designs, like the Rotrex, are of the "wet" type, that is, removing bath condensate and vapors in a single cylinder. The chief advantages of these types are:

(a) Low power consumption;

(b) Positive action and stability, and

(c) Ability to handle excessive air leakages.

6. While these later designs as represented by the Rotrex and Edwards are still excellent pumps for units up to 1,500 kw., for larger units it is necessary that the rotative speed be reduced, in which event they become both cumbersome and expensive and take up a large amount of space. The volumetric efficiency of these pumps varies from 60 per cent. at three inch partial air pressure, to 18 per cent. at 0.5 in. partial air pressure, and since they handle both the water of condensation and vapors, at high vacuum the partial air pressure soon becomes very low unless the condensate is refrigerated by flooding the lower banks of tubes in a surface condenser.

7. On account of the distinct advantages of this type, however, and particularly where the pump drive is combined with the circulating water pump, the writer feels that the merits of these improved old-time designs are often overlooked, especially for units up to 1,500 kw.

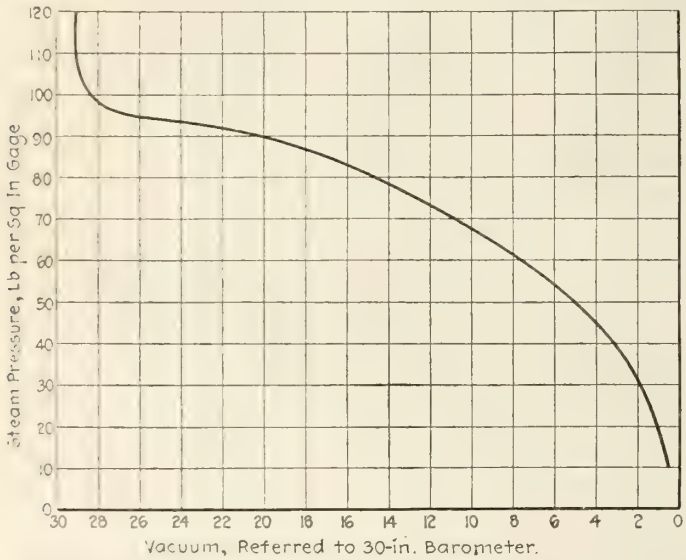
Dry-Vacuum Displacement Pumps

8. The next development was the separating of the handling of condensate and vapors, introducing what is commonly known as the "dry-air" pump. Wet-vacuum pumps of the type previously described were first used with a small quantity of water admitted for sealing purposes, a separate pump being provided to remove the condensate. Later the dry-vacuum pump made with small clearances and handling air only appeared, and this type has the same general advantages as the "wet" pumps but with better volumetric efficiencies. With improvements like flash ports, introduced by Wellner, to momentarily connect the clearance space at the end of the compression stroke with the vacuum side of the piston, both suction and discharge valves being closed, and using two-stage pumps with double and single cylinders, this type has held its own in the demands for high vacuum and increased sizes. And, except for its complications, the number of moving parts, maintenance, size, space requirements, etc., its use cannot be criticized.

9. The increase in the size of turbines coming into general use, however, together with the continuous demand for higher vacuum, called for dry-air pumps of cumbersome size and excessive cost, and the solution of this problem seemed to point to an ejector air pump of some form, using water as the motive fluid.

Hydraulic-Entrainment Air Pumps of the Rotary Type

10. In 1862 Christian Schiels, of Oldham, England, invented a hydraulic-entrainment air pump† which expelled the air from a condenser by combining or entraining it with hurling water in its passage through a fan or centrifugal pump. The necessary water pressure was provided by means of a high-speed rotary device and this, together with the relatively small space required and ability to maintain a high vacuum, offered such desirable features that, when the demand had exceeded the limitations of the dry-air pump, development came very rapidly. These pumps took two general forms. In one the air is entrained in the same chamber containing the rotating element, this type including a design of Leblanc's, manufactured by the Westinghouse Companies, which has given excellent results and is so well-known that a detailed description is not necessary. The A. E. G. pump is a modification of this type of pump and operates on almost the same principle.



VACUUM OBTAINED WITH SMALL-SIZED EJECTOR OF RADOJET TYPE WITH CONSTANT CAPACITY AND DECREASING STEAM PRESSURE.

11. The Hydrovac is another pump operating on the principle of entraining alternating slugs or layers of air and water in a combining element. The Thyssen pump performs its function by entrainment only, a centrifugal impeller discharging a thin sheet of water across a combining chamber into an annular diffuser, air being admitted to come in contact with both sides of the water sheet.

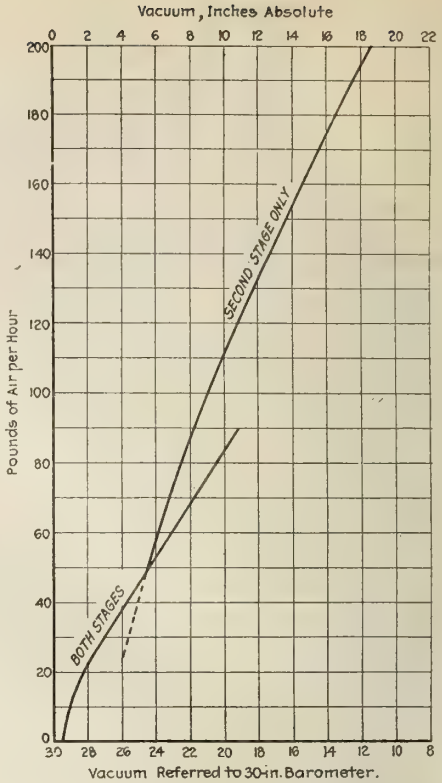
12. The Roturbo pump operates on a similar principle, except that numerous jets of water are discharged from a revolving pressure chamber across a combining chamber, and the resultant water and entrained air are collected in a revolving fan and directed into an annular diffuser and volute.

13. There are also numerous other designs of hydraulic-entrainment air pumps of the rotary type, such as the Globe-Johnson, Weir, and others, nearly all of which are subject to the same limitations.

Hydraulic-Entrainment Air Pumps of the Ejector Type

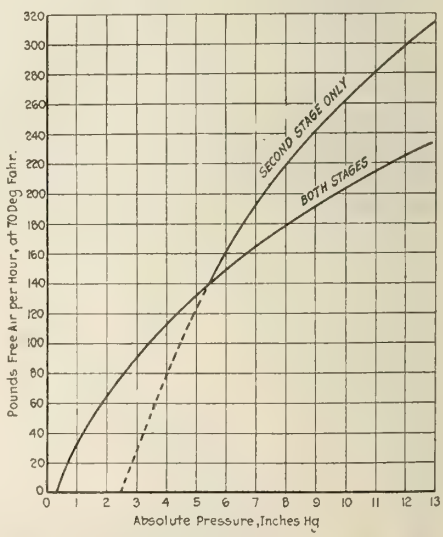
14. The other type of hydraulic-entrainment air pump is that in which the entrainment or compression of the air is performed in a part of the apparatus entirely separate from that producing the pressure of the hurling or entraining water. These pumps follow the simple ejector principle, using single or multiple jets of water discharging into a combining cone or diffuser and entraining the air due to the high velocity of the water jets. The Koerting ejector is the best known of this type, the water being supplied from an exterior source and forced through a number of nozzles into a combining cone or diffuser. These pumps serve their purpose best when combining the function of an air pump and a condenser, as then the steam condenses immediately on coming into contact with the water, increasing the effective head on the water nozzles and consequently the water velocity and entrainment. Under favorable conditions this type will be found satisfactory, its limitations being the amount of water that must be pumped and the necessity of keeping the nozzles thoroughly clean; for the pump must have water, and as it has very definite limitations in its air-handling capacity, it becomes very unstable when called upon to handle air in excess of the designed quantity. There are several modifications of this type of pump in use abroad, as represented by the Kinetic and others.

15. These water ejectors are occasionally used in series with some form of a steam jet which acts as a booster, and they usually take their water supply from a small centrifugal pump connected in parallel with the circulating system. The Muller or Worthington pump is a distinct design in that the jets are discharged from a rotating element into the diffuser, assuming a helical form with a decreasing pitch. The air is entrained and trapped between these jets and compression in the diffuser is aided by the decreasing pitch of the helically shaped jets of water.



VACUA OBTAINED WITH TWO-STAGE RADOJET EJECTOR WITH VARYING VACUA AND CONSTANT STEAM PRESSURE.

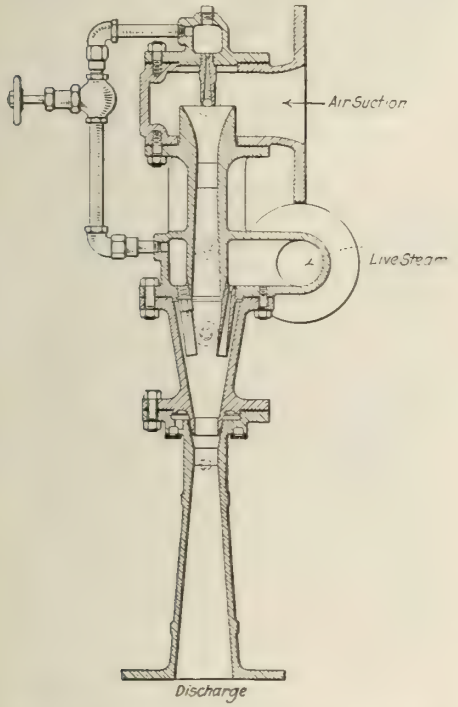
16. In general, the power required by a hydraulic-entrainment air pump is 40 per cent. greater than that for a rotary dry-air pump of the same relative capacity and the air-handling capacity is subject to strict limitations at moderate vacua; consequently these types cannot be counted on for overloads or unusual demands. The former is due to the



VACUA OBTAINED WITH ANOTHER TWO-STAGE RADOJET EJECTOR WITH VARYING

power required to move the necessary hurling water against a fixed discharge head, and the latter to the limiting weight of air that can be entrained by a fixed quantity of water. The volumetric efficiency of the dry-air pump falls off very rapidly at high vacua, due to the rarefied air to be handled in a fixed cylinder volume, through fixed port areas, and to the detrimental effect of the smallest clearances. The hydraulic pump is not so seriously affected; in fact, it improves in capacity at high vacua.

17 The hydraulic-entrainment type of pump has given complete satisfaction in performing the function demanded of an air pump, i.e., removing air and vapors from the condensing chamber and maintaing as low pressure as is consistent with circulating-water temperatures. But against the many advantages and satisfactory performances must be balanced the disadvantages. Hydraulic air pumps, using water as their



SECTIONAL VIEW OF LIBLANE EJECTOR.

working medium, are subject to erosion, and on account of the necessarily small passages, or sharp edges of vanes, presented to the water, must have clear, clean water of the falling off in capacity and efficiency is very rapid. In most cases these essential requirements necessitate a tank for the hurling water, screens and incidental attention thereto. And on account of the simplicity of the apparatus when compared with the rotary dry-vacuum pump, the admitted hgih power consumption has been accepted as a necessary evil and provision made to equalize the heat balance by providing electric drive for other auxiliaries.

Steam-Jet Ejector Air Pumps

18 The ejector principle is an old one, the use of steam as a medium and applied as a vacuum pump having been patented in England in 1868, but for high-vacuum service the ejector pump has not been in general commercial use in this country until the last three years. It is now, however, a definite engineering and commercial success, one manufacturer having actually delivered ejector pumps to serve over 4,000,000 h.p. of prime movers.

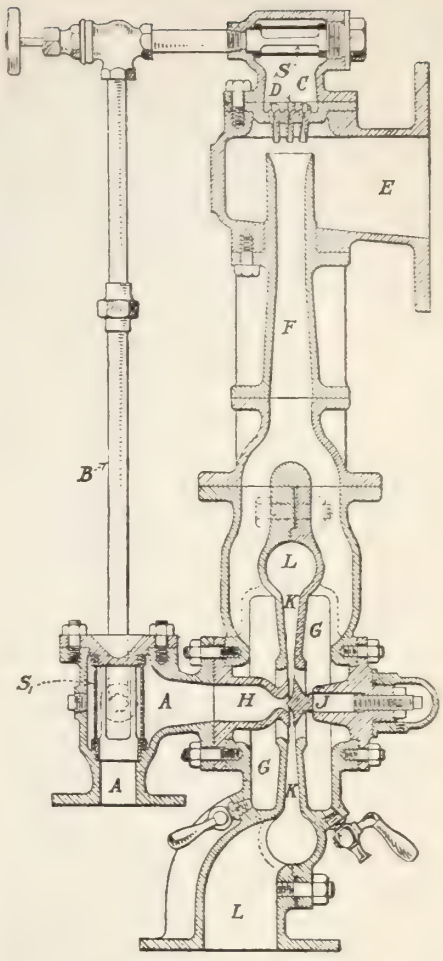
Advantages Claimed for the Ejector Air Pumps

19 Before outlining the development of the ejector air pump, the reason for its adoption may be considered by reviewing the advantages claimed for it, namely,

a Extreme simplicity
b No maintenance or attention
c Reliability and flexibility
d Stability
e Minium space and weight
f Low steam consumption, high efficiency.

20 The first advantage enumerated, while the most important, may be passed over as obvious. The second advantage results from the fact that there are no moving parts to wear out. The parts subject to wear are steam nozzles and diffusers, and the medium used is the same as used in the turbine; therefore the life of the pump, as far as its wearing qualities are concerned, should be as long as that of the nozzles of the turbine it serves. Because there are no moving parts to oil or adjust, the only attention required is that of opening and closing the valves controlling the pump.

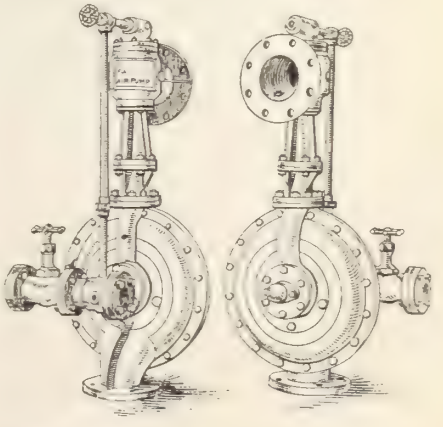
21 The third advantage claimed is one that will carry the most weight with engineers in charge of power production, because with them continuity of service is of first importance. As is well known and shown later, the air leakage varies greatly and provision must be made for leakages largely in excess of those expected with good operation. With other types of air pumps than those being considered, particularly rotary dry-vacuum pumps, it is usual to provide a pump large enough for maximum requirements and operate at reduced speed or displacement. This has the serious objection of making the entire unit dependent on a single air pump operating inefficiently. With ejector-type pumps, on account of their small size, weight and space requirements (no foundations being required), the total estimated air-removal capacity can be provided by two or more units, one or more of which can be operated as required, thereby providing maximum efficiency and insurance against shut-down. And the size of units can be so selected that one only is sufficient with a tight condensing system. Another desirable feature is that the necessity of using a second pump is an indication that unusual air leaks exist, and a third advantage is the maximum steam economy resulting from only as many pumps being used as are actually required. The adoption of ejector air pumps by the navies of the United States and France and by the United States Emergency Fleet Corporation supports this third claim.



SECTIONAL VIEW OF RADOJET AIR PUMP.

22 As to stability, while engineers have raised the question in regard to the single-stage water or steam ejector, attention may be called to Fig. 1, which gives test results of a small-size two-stage ejector to the Radojet type with constant capacity and decreasing steam pressure. Figs. 2 and 3 show variations of capacity of two sizes of these ejectors with varying vacua and constant steam pressures. Similar results are regularly obtained in operation of priming pumps, also with pumps attached to other than condensing equipment.

23 The fifth claim is clearly demonstrated by the following comparative figures for weight and floor space re-



EXTERIOR VIEW OF RADOJET AIR PUMP.

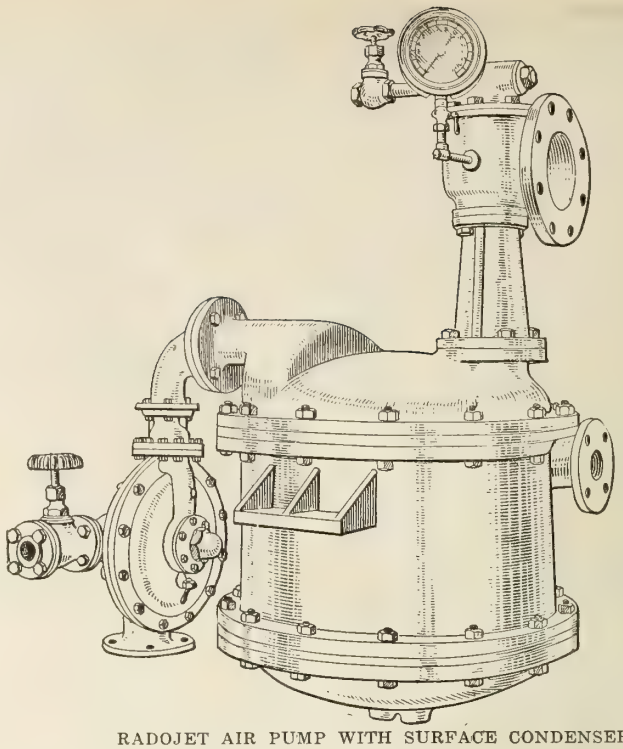
quired by three types of pumps for use with a 7,500-kw. surface condenser:

Type of Pump	Floor-space	Wght. lb.
Rotary dry-vacuum	10′ x 22′	31,000
Hydraulic	5′ x 10′	6,300
Ejector	1′ x 1′	450

24 The sixth claim requires the most consideration because it leads the list of disadvantages put forth by the few who have opposed the use of ejectors. Based on wasting all the steam used by the air pump (and the writer does not know of a modern power plant designed on this basis), it is freely admitted that the ejector requires more steam than the rotary dry-vacuum or wet-vacuum pump. If there is a case where all the steam used by the air pump cannot be used in heating feedwater, intercondensers can be used between the stages, resulting in a steam requirement less than that of the rotary dry-vacuum or wet-air pump. This alternative, however, requires some investigation. The operating steam in passing through the nozzles does work in entraining and accelerating the velocity of the air, and increases its temperature and compresses it. There is a small amount of heat lost, due to friction through the diffusers, which may be considered negligible. Excepting this the whole of the heat in the steam is available for heating boiler feed-water, the heat in both the steam and air doing useful work. With a 10,000-kw. surface-condensing equipment the condensate would be raised approximately 10 deg. by this means. Compare this now with the rotary dry-vacuum pump, hydraulic pump and ejectors with intercondensers. With the first the heat imparted to the air by compression (dry air at 60 deg. Fahr. compressed from 2 in. absolute pressure to atmospheric pressure has a final temperature of 680 deg.) is transmitted to the jacket or hurling water and wasted, as is the heat imparted to the hurling water in hydraulic air pumps.

25 With the intercondenser ejector approximately 30 per cent. of the total steam is used in the first stage and is seldom conserved. With jet intercondensers of the Briguet type, where air is admitted into the suction of the second stage, the operation is further complicated. Another objection to the intercondenser type is that the condensed steam from the first-stage nozzles must be removed from a chamber under vacuum, and the system is further complicated by cooling-water lines to and from this intercondenser. When a thermal efficiency of 90 per cent. and over is obtainable, and that with a total steam consumption that need not exceed 1 per cent. of the total steam used, then the claim seems established.

26 As a general rule, for plants of ordinary size (excluding units of 20,000 kw. and over, where better results are obtainable), it may be said that with ejectors without intercondensers less than 1 per cent. of the total steam consumption is required for surface condensers, and from 2½ to 3 per cent. for jet condensers; for intercondenser ejectors the percentages are approximately one-half these values.



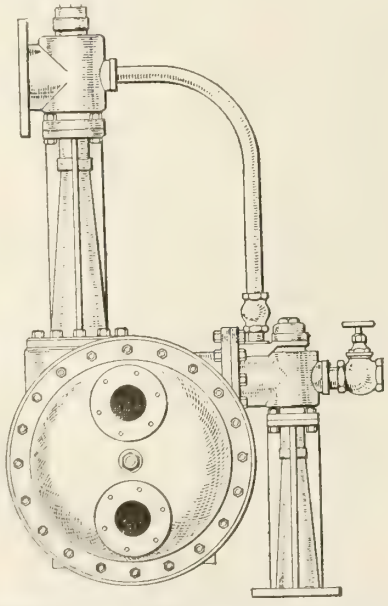
RADOJET AIR PUMP WITH SURFACE CONDENSER.

27 In 1903 Parsons brought out his steam-ejector vacuum augmenter, which was one of the first commercial uses of the steam-jet ejector as an exhauster of air under high vacuum. While it dealt with vapor, at low partial air pressures, the compression was only one or two pounds and therefore it is not comparable with modern pumps.

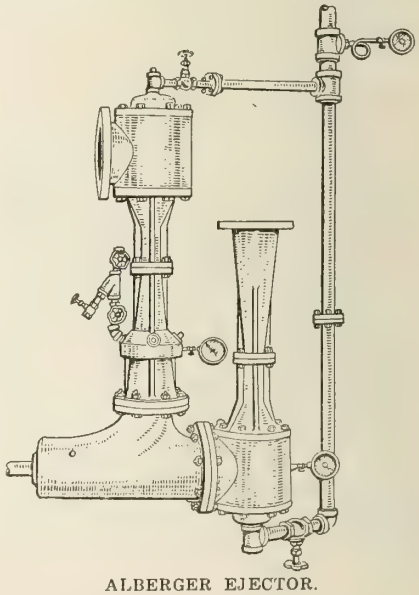
28 Parsons' application is to withdraw the vapors from the condenser and compress them 2 to 4 in. abs., condensing the steam used in an auxiliary condenser and discharging the compressed vapors into the suction of the wet pump which operates against a reduced vacuum by reason of an artificial head of condensate being provided.

29 One of the early developments of the ejector using steam jets in series for high vacuum was by Leblanc for his refrigeration system. He was able to obtain an absolute pressure of 0.05 in. Hg, and later applied his design to air pumps for condensers with marked success, although the Westinghouse Company, the licensees in this country, have confined their installations to marine use. The general design is shown in Fig. 4.

30 This ejector has a single nozzle in the first stage which entrains the air and compresses it in the diffuser, from which it is discharged into a mixing chamber where it comes in contact with



WHEELER CONDENSER AND ENGINEERING COMPANY EJECTOR.



ALBERGER EJECTOR.

the steam from a large number of nozzles of the second stage, the steam and air from the first stage being entrained and compressed to atmospheric or discharge pressure in the second diffuser.

31 It is well known that ordinary single-stage ejectors work best and are most stable when the compression ratio is approximately one to seven, and it is for this reason that two stages are always employed in steam-ejector air pumps. The ratios of compression in the two stages should be kept as nearly equal as possible, although for maximum economy over varying loads it is found in practice that the best results will be obtained by making the ratio of compression in the first stage equal to or greater than that in the second stage. It can be shown that for maximum efficiency in the utilization of kinetic energy of the motive fluid the ratios of the weights of fluid compressed and motive fluid used should be as nearly equal as possible. This, however, is a condition which a few experiments with steam ejectors will show unattainable.

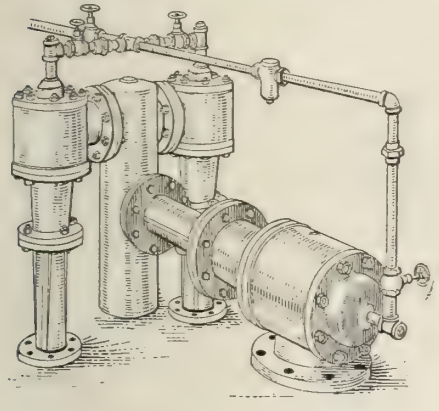


FIG. 10 CROLL-REYNOLDS EJECTOR

32 As has been mentioned before, hydraulic air pumps operate almost entirely by use of the kinetic energy of the motive fluid. The entrained water vapor carried over with the air condenses on coming in contact with the water and uncondensable vapors are entrained, either between sheets or with small globules of water and compressed by kinetic energy in the diffuser.

33 The action in a steam ejector is somewhat different, where there is a fluid to be compressed, moving at a very low velocity, which must be acted upon by steam issuing from nozzles at velocities varying from about 3,000 to 3,500 ft. per sec. It is quite evident, then, that the operating steam must entrain the air by friction, and also that a maximum entraining surface of the operating steam is of prime importance.

34 This means that either a number of small cylindrical nozzles must be used, or some special form of nozzle be substituted to give a greater superficial area per unit of steam used. This is of most importance in the second stage, where 70 per cent. or more of the steam is used, and may be accomplished in any one of three ways. The first method, that of using a large number of small nozzles, is objectionable on account of the difficulty of obtaining effective entrainment with the nozzles in the center of the group. And where the nozzles are placed concentrically or surrounding the first-stage diffuser, only half of the exposed steam area is effective.

35 In the second method a concentric steam nozzle is employed. This nozzle is sensitive to pressure fluctuations and exposes only a small portion of its superficial steam area to contact with the air.

36 In the third method, using a single steam nozzle in which an adjustable nozzle point spreads out the jet and causes it to flow radially as a thin sheet of steam, the air is entrained on both sides of the sheet and compressed in a radial diffuser surrounding the nozzle. This is the general form of the Radojet air pump illustrated in Figs. 5 and 6.

37 Referring to Fig. 5, steam is admitted from the boiler to the strainer cage *A*, a part being passed through the pipe *B* and strainer *S* to the first-stage nozzle chamber *C*. The steam expands in the nozzles *D* and passes across the suction chamber *E* at a velocity of approximately 3,000 ft. per sec., entrains the air and the vapors from the condenser and compresses them in the diffuser *F* to a higher absolute pressure. The mixture of steam and entrained vapors passes into a double passage *G* so arranged as to come into contact with both sides of the sheet of steam, and issues radially from the second-stage nozzle. Steam is simultaneously delivered through strainer S_1 and nozzle throat *H* to contact with the nozzle point *J*, which spreads the steam radially into a thin sheet issuing at a high velocity and passing across the mixing chamber *G*, entraining the commingled air and steam (or the air only, where an intercondenser is used) and carrying them into the annular diffuser *K* where the mixture is compressed to atmospheric or discharge pressure and then discharged through the volute and opening *L*.

38 From 70 to 90 per cent. of the total steam used passes through the second-stage nozzle. The thin sheet of steam issuing radially from the adjustable nozzle point *J*, by having both sides of the sheet in contact with the air to be entrained, exposes the maximum surface possible for entrainment and secures for this design the highest efficiency and economy. The nozzle point *J*, being adjustable, permits of varying the cross-section of the nozzle passage and changing the expansion ratio of the steam. This is a factory adjustment and made to secure the maximum efficiency of each individual pump. The first-stage nozzles and both diffusers are made of bronze and the second-stage "Radojet" of special steel. The parts described show absolutely no wear or erosive effect in service.

39 Ejectors with and without intercondensers are now made by practically all of the condenser companies, various designs being shown in Figs. 7 to 10.

40 Fig. 7 shows a Radojet pump with a surface intercondenser. Two or more pumps can be mounted upon a single surface condenser, division walls being made in the steam boxes so that each pump may be operated independently. These individual pumps may vary slightly in size so that different combinations of air-removal capacities can be obtained. Such an arrangement is now being followed with a 30,000-kw. installation at Detroit.

Selection of Air-Pump Capacities and Sizes

41 The selection of air-pump capacities and sizes has always been shrouded with considerable mystery and the methods to employ should be given more publicity. Air is admitted to the condensing chamber in three ways:

a From leaks in the system, under vacuum
b From entrained air in the boiler feedwater carried over with the steam, and
c From entrained air in the injection water (in jet or barometric condensers only).

42 The sizes of air pumps to use with surface condensers, where only *a* and *b* in the preceding paragraph apply, will be considered first. The early air pumps were of the wet type, and textbooks and handbooks of not many years ago gave a rule that the displacement of the air pump should be a function of the low-pressure cylinder displacement. And on this basis, or on the proportions of a successful installation, most air-pump sizes were then selected. Later a rule making the displacement a function of the volume of condensed steam was very generally used and proved to be very satisfactory. This called for ratios of swept displacement of the air-pump cylinder to the volume of condensate of:

20: 1 for 26 in. vacuum
20: 1 for 27 in. vacuum
40: 1 for 28 in. vacuum
53: 1 for 29 in. vacuum.

For rotary dry-vacuum pumps of good design the ratio of displacement to volume of condensate for 28 in. vacuum seldom exceeds 35 to 1.

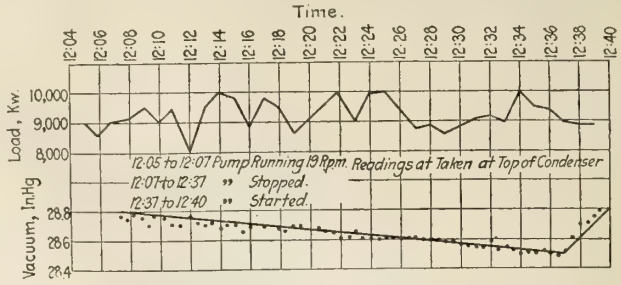
43 The introduction of ejector pumps using water or steam required that some other method of selection be used. And the adaption of ejector and entrainment-type air pumps and the general use of large units also called for a more accurate method of selection of sizes. For a number of years experiments and investigations have been made on the effect of air leakage on vacuum, heat transfer, etc., all of which have indicated that the presence of only a small amount of air has a very detrimental effect. The relative coefficient of heat transfer as referred to steam was shown

by Josse, to be 1 to 700. This caused the large operators to introduce periodic tests of their condensers for air leakage, which was accomplished by discharging the rotary dry-vacuum pump into a gasometer.

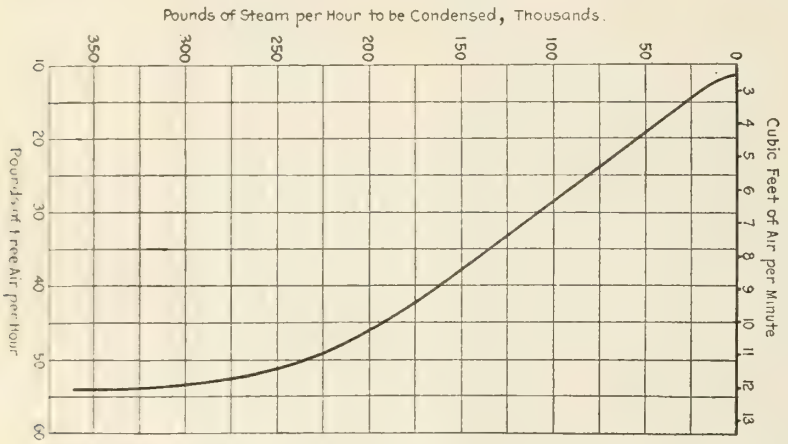
44 These periodic tests showed some unexpected results: That a 30,000-kw. unit need not necessarily have a greater air leakage than a 20,000-kw. unit, and that it was possible to keep air leakage to extremely low quantities, dependent (*a*) on the care exercised in installing the condensing equipment and (*b*) on the care in operation, or rather the willingness of the operating engineer to go after small leaks. That a system can be made practically air-tight can be demonstrated by shutting down the air pump while the unit is under load, Fig. 11 showing results as reported on a 10,000-kw. unit at the Boston Elevated Station. Here a drop of only 0.30 in. Hg in 30 min. indicates that there was very little entrained air in the steam and practically no air leakage.

45 The purchaser of a condensing equipment insists that the manufacturer guarantee the vacuum, but with his inquiry, in which he specifies the amount of steam to be condensed, water temperature, etc., he neglects to state how much air he intends shall be allowed to leak into the system. And the writer contends that this is almost as important a factor as the quantity of steam. For this reason the condenser manufacturer is compelled to do a great deal of "educated guessing." We know that with the ordinary system, using open feedwater heaters, the amount of air mechanically entrained in the feedwater is reduced to 1 per cent. or less. Orrok[1] showed reductions of entrained air from 4.325 per cent. in raw water to 0.931 per cent. in the heater. The air quantity from this source is in direct proportion to the quantity of steam condensed. Leakage through glands, joints, connections and the materials of which the condenser and the low-pressure stages of the turbines are made, is a function of its size and tightness. Assuming the same care in manufacture and make-up, then size also is a function of quantity of steam condensed and we may assume total air leakage as a factor of the quantity of steam condensed.

46 In arriving at our figures there are some very uncertain factors to be taken into consideration: Shall we assume the best operation possible, weekly tests for leaks, etc., or the operation of a shiftless attendant satisfied with a spring gage? Inasmuch as the manufacturer is interested in the prosperity of his customer, he assumes the former, and to be sure of his own guarantee, provides for the latter. It is generally known that under good operative conditions the speed of a rotary dry-vacuum pump can be cut to one-half its rating, and that there are other times when the full capacity is needed. It is therefore excellent practice to supply air pumps of capacity in excess of the anticipated requirements.



CURVES SHOWING EFFECT OF SHUTTING DOWN THE AIR PUMP WHILE UNIT IS UNDER LOAD.



ESTIMATED QUANTITY OF AIR TO BE REMOVED FROM SURFACE CONDENSER WITH TIGHT SYSTEM AND GOOD OPERATION.

Dry-Air Leakagae in Surface-Condensing

47 Based on a *tight system and first-class operation,* the amount of *dry*-air leakage to be expected with surface-condensing equipment is shown in Fig. 12. It should be noted that this is dry air and is less than the capacity to be provided by the air pump, because in passing through the condenser this air becomes saturated and the air pump must remove with the air an amount of water vapor dependent on the pressure and temperature of the mixture.

48 It will also be noted that the air-leakage curves in the figure are indicated in pounds of air per hour. This is done because a pound of air is a definite thing—a cubic foot of air must be specified as to temperature and pressure to have a definite meaning. To those accustomed to thinking in terms of cubic feet the approximate relation of 4.5 lb. of air per hour to 1 cu. ft. of air per min. at 70 deg. fahr. and atmospheric pressure, will be of some assistance.

49 According to Dalton's Law, the total pressure in the condenser is the sum of the partial vapor pressure corresponding to the temperature of the mixture, as taken from the steam tables, and the partial air pressure due to the air or other gas present in the condenser. The volume of the air is directly pro-

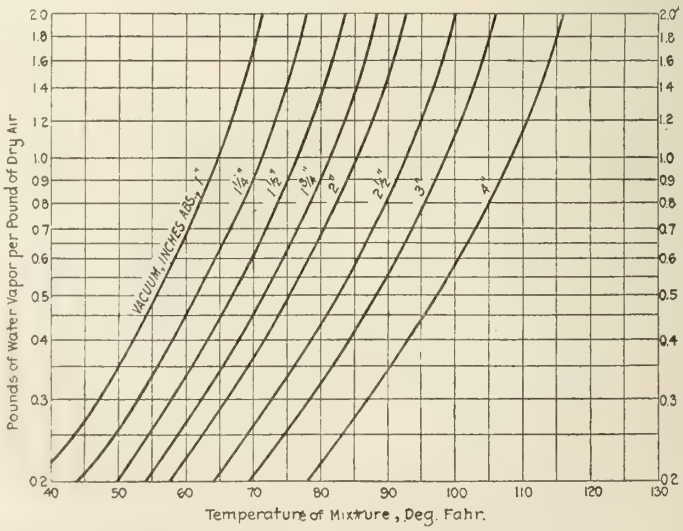


CHART SHOWING WEIGHT OF WATER VAPOR THAT MUST BE REMOVED FROM A CHAMBER CONTAINING WET AIR AND VAPOR TO REMOVE ONE POUND OF DRY AIR AT DIFFERENT TEMPERATURES AND PRESSURES.

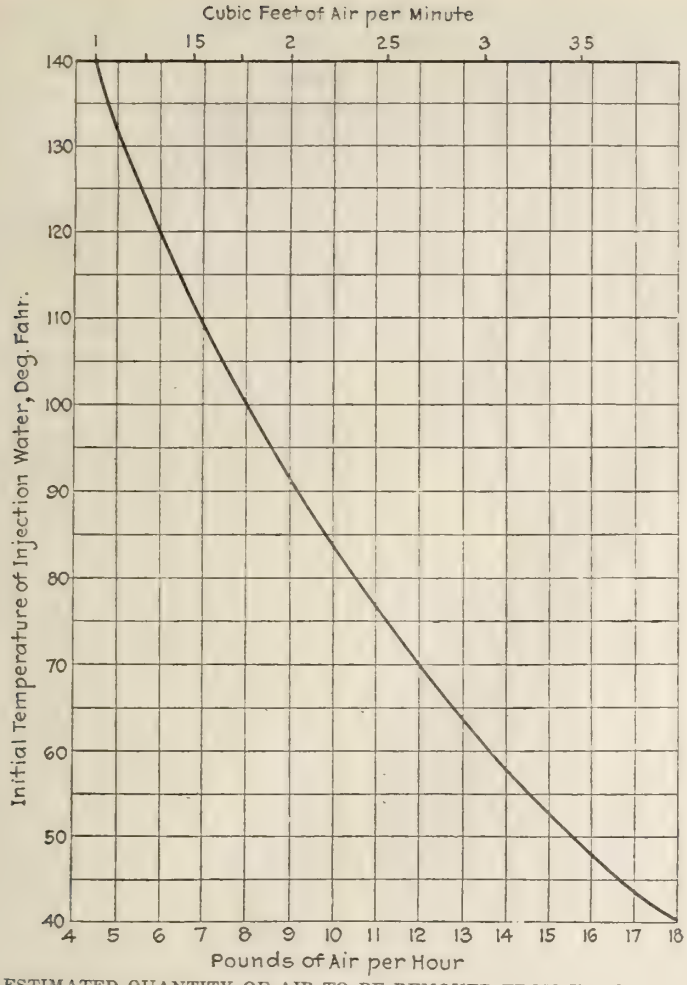


ESTIMATED QUANTITY OF AIR TO BE REMOVED FROM JET OR BAROMETRIC CONDENSER PER 1,000 GALLONS INJECTION WATER PER MINUTE.

portional to its absolute temperature and inversely proportional to its pressure; therefore, if the mixture of air and water vapor in a condenser is cooled, the total pressure, or vacuum, remaining the same, the vapor pressure is reduced and the partial air pressure increased, with corresponding changes in volume.

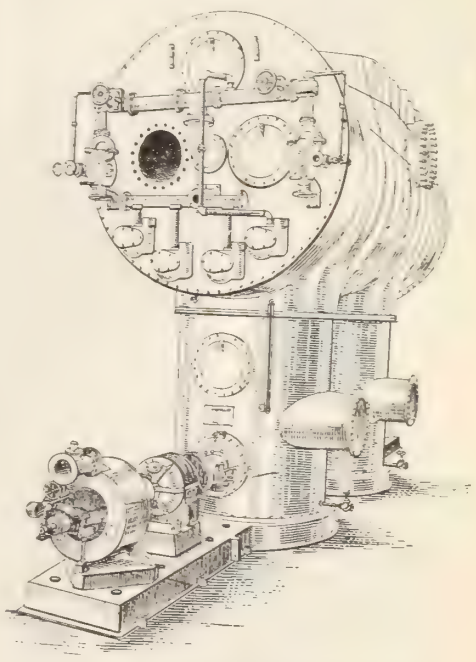
50 For example, 1 lb. of a mixture of air and water vapor at 80 deg. fahr. and 2 in. absolute pressure as extracted from a condenser would be composed of 0.595 lb. of air and 0.405 lb. of water vapor. Let this mixture be taken from a colder part of the condenser so that its temperature is reduced to 70 deg. fahr., and the relative weights will be changed to 0.724 lb. of air and 0.276 lb. of water vapor; or, to do the same effective work an air pump with a displacement only 0.595/0.724 or, approximately, four-fifths as large would be required. The problem may also be considered as the determination of the total weight of saturated mixture that must be removed from a condenser to extract 1 lb. of dry air, and Fig. 13 has accordingly been plotted to show the weight of water vapor that must be removed from a chamber containing saturated air and vapor to remove 1 lb. of dry air at different temperatures and pressures. These factors must be used in conjunction with Figs. 12 and 14.

51 For example, assume a 10,000-kw. surface condenser condensing 140,000 lb. of steam per hour, with circulating-water temperatures of 60 deg. in and 74 deg. out, a vacuum of 1.5 in. abs. being maintained.

52 From Fig. 12 it is seen that the expected dry-air leakage with a *tight system and with good operation* is 36 lb. per hour. Under these conditions and with good design the temperature of the mixture going into the air pump should not exceed a mean of the circulating-water temperatures, or 67 deg. with a vacuum of 1.5 in. abs. Fig 13 shows that in order to remove 1 lb. of air it is necessary to remove 0.5 lb. of water vapor. Therefore the air pump must have a capacity of 1.5 × 36 or 54 lb. per hour of a mixture of air and vapor at a pressure of 1.5 in. abs. to take care of a leakage of 36 lb. of dry air. Now this capacity is selected on the assumption of a tight system and good operation, and does not provide for emergencies. The usual way to provide for emergencies, unusual operating conditions and excessive air leaks is to select a larger pump and operate at reduced capacities, but the better way by far is to select two pumps of minimum size as indicated from capacity curves. There are several good reasons for this: A spare pump is provided as an insurance against shutdown; maximum economy of power is obtained; and the necessity of the use of both pumps is an automatic indication of excessive air leakage. The steam ejector being so small and not requiring foundations, lends itself most admirably to this selection and can be used in two or as many more units as are desirable, to provide for fractional loads and maximum economy.

Selection of Air Pumps for Jet and Barometric Condensers

53 In selecting an air pump for a jet or barometric condenser, capacity must also be provided for the entrained air and gases which enter with the injection water and immediately expand to the pressure being maintained in the condenser. Here we have a very uncertain item, for cold water will hold more air than hot water, and water flowing over leaves and decayed vegetable matter absorbs CO_2. The air content will be different in the water of a spray pond or a still lake, or of a slow-moving river or a mountain stream, and will vary under ordinary conditions from 1 to 5 per cent. by volume. The quantity of air admitted into the condensing system with the injection water is greatly in excess of that entering with the steam and air leaks, and a considerable quantity of air passes out of the system through the water-removal pump or down the tail pipe by entrainment. This latter quantity is sometimes as large as 40 per cent. of the total and seldom less than 20 per cent. It is therefore assumed that the air admitted with steam and by leaks in the system passes off with the injection water, and air-pump capacity is provided only for the air entering with the injection water. Taking all these variations into consideration, *dry*-air-re-



1500 K.W. JET CONDENSER WITH FOUR RADOJET AIR PUMPS.

moval capacity for either a low-level jet or barometric condenser should be provided as shown in Fig. 14, using as before the factors the factors from Fig. 13.

54 In this case it is advisable to select two or more pumps so that the total capacity is that obtained from the curve. The ejector pump lends itself to the best advantage in this selection and provides flexibility and economy when the air entrained in the injection water is not as great as anticipated.

55 To illustrate the selection of an air pump for a low-level jet condenser, assume a 7500-kw. unit condensing 110,000 lb. of steam per hour and maintaining a pressure of 2 in. abs. when supplied with 9,000 gal. of injection water per min. at 70 deg. Fahr. Fig. 14 shows that we can expect to remove 12 × 9 or 108 lb. of air per hour from the condenser. Assuming the mixture going to the air pump has a temperature of 75 deg., it is seen from Fig. 13 that with this temperature and a pressure of 2 in. abs. it is necessary to remove 0.49 lb. of water vapor in order to remove 1 lb. of air. Therefore the air pump must have a displacement of 1.49 × 108, or approximately 160 lb. of mixture per hour at 2 in. abs. To provide this capacity in a single unit would require inefficient operation at partial loads, or when the air leakage and content in injection water is not as great as provided for. To use two or more units is also better practice, as then the entire equipment is not dependent on a single air pump. Fig. 15 shows a 15,000-kw. jet condenser provided with four Radojet having a total capacity obtained as indicated in the foregoing example.

56 Most steam-ejector air pumps have their nozzles designed for a fixed initial and back pressure, a pressure-regulating valve being installed in the steam supply line to automatically take care of boiler fluctuations. The maximum back pressure usually specified is 0.5 lb. gage, but this may be increased to a maximum of 3 lb. by increasing the initial steam pressure at some sacrifice in steam economy. Ordinarily, steam-ejector air pumps should be exhausted under water into a surge or feed tank so that the entire heat in the steam and air can be utilized, and the entrained air passed off through a vent. The exhaust can be into an open feedwater heater without detrimental effect, provided the heater is thoroughly vented, and also can be piped to any reasonable distance, provided pipe sizes are so selected as not to produce excessive back pressure. If the exhaust discharge is above the air-pump exhaust opening a barometer trap should be provided at the lowest point of the exhaust line, and of such length as to balance the predetermined back pressure. And a check valve should always be installed in the exhaust line from each ejector.

57 There is nothing to get out of order, to oil, or to adjust about this type of pump, and if the screens and nozzles are inspected and cleaned occasionally, the owner of a condenser equipped with steam air ejectors can be excused for exclaiming, "Why didn't some one think of this before?"

Sold Outfit.—The Hanson Van Winkle Co. have just sold to the Kelsey Wheel Co., of Walkerville, a large generator plant, including a 2,000 amp. dynamo, which they are using for electro-plating automobile wheels and accessories.

Chatham's Water.—At a meeting of the Chatham Water Commissioners it was decided to submit a referendum to the ratepayers of Chatham at the earliest possible moment asking them to decide between Lake Erie and the River Thames as the permanent source of a civic supply of water, with the understanding that the city council will apply to the Railway and Municipal Board for permission to issue debentures for raising money to carry into effect the scheme selected.

Sold Property.—The Gurney Foundry Company have sold No. 740 and 742 Yonge Street, Toronto, but as yet the name of the purchaser is not disclosed. The sale price is reported to be around $90,000 and the lot has a frontage of 33 feet by a depth of 325 feet to Balmuto Street.

Selling Stock.—The Dillon Crucible Alloys, Ltd., are advertising in the Welland paper, giving to citizens an opportunity to buy a small block of stock, which will pay dividends of not less than eight per cent., at the price of $100 per share, cumulative preferred, with bonus of 50 per cent. common at $5 per share; for instance, $1,025 would buy ten shares preferred and five shares common.

Welding is Steadily Gaining Favor in Boiler Industry

By ARTHUR MALET

THERE is no question but that welding in general and oxy-acetylene welding in particular is steadily gaining in favor in the boiler industry, as is evidenced by the number of shops in which its use is gradually being extended in regular production.

This interesting statement is made by the above author in a recent issue of Acetylene Journal; and he goes in the following manner: .

Although it has been condemned by some individuals, the causes of failures of oxy-acetylene welding are generally traceable to the inexperience or poor workmanship of the operator. To become a good welder or to be efficient in any line of work, it is necessary that a man must like that work and try his hardest at all times to produce the best results of which he is capable.

In the case of oxy-acetylene welding, the operator must study the action of the metal when subjected to the intense heat produced by the flame and understand why the welding progresses as it does. He must watch his flame and keep it neutral and be sure that he is actually welding and not simply sticking the metal from the filler rod on to the piece being welded. He must learn how to handle his torch and the filler to the best advantage. He must also be a cold-blooded sort of chap to be able to stand the intense heat in which he must sometimes work if he is welding a piece surrounded by a bed of red-hot coals, as happens when preheating is necessary.

In the shops where the writer is located the torch is put to every possible use in the work. In its cutting capacity it is used to burn out all staybolts and old sheets and to cut all rivets. If the operator is careful, he can bevel the sheets to be welded with the cutting torch and save time and labor that would be required to do the same work with a chisel and air hammer.

Ash pans are in a great many cases welded now and seem to give as good service as pans with angle irons and rivets. In building up ash pans the pieces of plate may be riveted to the casting before or after welding. The sides of the pan are held together at the top by a wire clamp. Before the welding is started, thin wedges are driven between the edges of the plates, forcing them apart about ¼ inch.

All tool boxes used by the engine crews are welded. These boxes are built up of No. 12 gauge sheet iron and are 18 inches long, 8 inches wide and 8 inches deep. Welding is done from the inside, the outside edges being smoothed after the operation is completed.

The great speed that can be accomplished in doing any of this shop work by means of welding is very much in favor of the process.

Recently it was necessary for the men in the shop to put a patch in the left back mudring corner of an engine. The patch was to cover an area which included two staybolts, eight mudring rivets on the door sheet, and three mudring where it lapped on to the side sheet, and three rivets in the running seam. It took just eight hours for a boiler maker, a helper and a welder to remove the old piece and weld the patch into place. All that remained after this was to drill the holes for the mudring rivets, drive the rivets, apply the two staybolts, and chip and caulk the patch.

Incidentally, the cutting torch was used to burn off the staybolts and the old sheet, as well as to preheat the patch when it was being laid up.

As yet we have not had to install any new side sheets or flue sheets, but probably will in the near future. When this becomes necessary we intend to try cutting out the top of the back flue sheet just below the braces and weld in a new top piece, as several of the flue sheets are badly worn in the tube area, but perfectly sound below.

Board of Trade Reports on Furnace Failures

C. E. Stromeyer, Chief Engineer of the Manchester Steam Users' Association (England), Discusses Some of the Features of These Reports

MY enquiry, in the 1916-17 Memorandum, into the strengths of shell plates suggested the desirability of reviewing the enquiry of 1899. I then dealt with 172 Board of Trade Reports. An additional number have come to hand since then, but by selecting only those cases in which the furnaces were not supported either by stays or cross tubes, the number has been materially reduced and the problem simplified.

It resolved itself into the two questions: Does the quality of furnace plates deteriorate in the same way as the quality of shell plates? and what is the weakening effect of local corrosion?

Forty Board of Trade Reports, which seem to throw light on these points, are contained in Tables III. and IV., and are fairly complete as regards essential details. Forty-eight other reports on the same subject are deficient in details and are enumerated further down. They include a few collapses, which are fairly complete as regards detail, but which seem to have been due to other causes than stated by the Board of Trade. Particular interest attaches to those cases, of which there are eight, in which the boilers had been subjected to hydraulic pressures without collapses taking place. These tables also contain a few cases of collapses of oval furnaces.

Unfortunately for the present enquiry, it is more difficult to deal with furnace plates than shell plates, because the theoretical bursting stress of a shell is also the ultimate tenacity as found with a testing machine, whereas the collapsing stresses of furnaces depend not only on the crushing strength of the material, but also on the ratio of plate thickness to furnace diameter and on its length. The most popular formula dealing with this relation is associated with the name of Fairbairn, who, it will remembered, made a number of tin-plate tube experiments while he was president of the Manchester Steam Users' Association. Those experiments threw much light on this complicated subject, but his formula and other similar ones have not been found quite satisfactory. Representing the test results by hyperbolas, as they do, necessarily demands limiting rules, because otherwise very short furnaces would appear to be infinitely strong and long furnaces would have no strength at all. A more comprehensive formula, which covers all lengths from nothing to infinity, which was suggested by me in 1899, has been found very useful, and serves as a convenient basis for the present enquiry:

$$S_H = 3 + \frac{13}{1 + \left(\frac{l}{t}\right)^2 \frac{1}{13{,}000}}$$

Here l and t are respectively the length of the furnace between supports and the thickness of the plate, both measured in inches SH is the compression in tons in the furnace plate at which collapse takes place. This formula has been slightly modified and simplified as follows:

$$S_H = 3 + \frac{13 \cdot 5}{1 + 3\left(\frac{L^2}{t^2}\right)}$$

L and t being measured respectively in feet and sixteenths of an inch. This formula, as will be seen by the three following cases, is in fair agreement with actual experiences, though they are unfortunately very few in number.

Board of Trade Report No. 314.—In this case the furnace did not collapse until the bursting pressure of the shell had been reached. This pressure of 212 lbs. was estimated from the boiler dimensions, a procedure which was justified by the fact that the riveted seams of the shell were found to have slipped before rupture took place. The furnace dimensions were 29 in. diam., 26.5 ft. length and ⅜ in. thickness. The stress at which the furnace should have collapsed according to the above formula was 3.16 tons per square inch. It actually withstood a 12 per cent. higher pressure of 3.57 tons.

Board of Trade Report No. 1,173.—This was a marine boiler which exploded while the safety valves were being adjusted to a pressure-gauge which was not in working order. The safety valves were found after the explosion and tested, and it was ascertained that they lifted at a pressure of 257 lbs. per square inch. As the valves were blowing at the time of the explosion, 257 lbs. was the bursting pressure. The furnaces were 34 in. diam., 6¾ ft. long., and the top plate thickness was 7-16 in., the bottom plates being ½ in. thick. The stress in the furnace plates at the time of the shell explosion was, therefore, 4.43 tons per square inch. Introducing the several values into the above formula, we find that the furnaces should not have collapsed until 6.57 tons per square inch had been reached. If, as is possible, the furnace plates had been reduced in thickness to ⅜ in. the stress would have been 5.16 tons at the time of the explosion, and the estimated probable collapsing stress 5.80 tons per square inch.

Board of Trade Report No. 2,349.—This was a Rastrick boiler with a vertical flue 38 in. diam., 3 2-3 ft. long between flanges, having 7-16 in. thick plates. The junction valve between this boiler and the steam pipes had been closed unbeknown to the engineer, who thought that the blowing of the safety-valves was due to a leaky seat. He, therefore, heavily overloaded the valve, which nevertheless continued to blow. With the help of the added weights, which were found after the explosion, it was estimated that the steam pressure under which the flue collapsed was 150 lbs. per square inch. Under this pressure the stress in the flue plate would be 6.51 tons per square inch. The stress estimated by the formula under which the flue might be expected to collapse was 6.03 tons per square inch.

These three cases are too few for the drawing of a very definite conclusion as to the correctness or otherwise of the formula, but they show that it can be used as a standard of comparison, to be modified in the light of the information collected in the present tables.

The furnaces in Tables III. and IV. gave way, due to local corrosion, and the important question to be considered is, does the general rigidity of the furnace as a whole determine the limit of stress under which the weakest section will give way, or does the strength of the furnace depend only on its weakest section? The problem is analogous to that of a strut with which furnaces have often been compared, the only difference between the two cases being that in a column the line of thrust between the load and the base is a straight line passing down the axis of the column, whereas in a furnace, which is really a complete arch pressed from all sides, the line of thrust is a circle passing along the centre line of the plate. Now it has been found for columns that up to a certain limit of load the column will always straighten itself again if through any accidental cause it may have been slightly bent. However, when the load exceeds a certain limit the column will not recover itself if accidentally bent, but will collapse completely. Similarly a cylinder will recover cylindrical shape if the external pressure does not exceed a certain limit, but will collapse under the slightest deforming influences if the external pressure exceeds that limit.

These conditions would not be changed by a local weakness such as a saw cut, in either the column or the cylindrical ring, except that, as the section at the saw cut is a reduced one, and the average stresses across the section are far more intense than the average stress, the limit for the load or thrust should be reduced in proportion to the reduction of the section. In other words, the permissible stress across the smallest section has to be determined by the average dimensions of the column or furnace. Thus, if the collapsing stress of a new furnace has been determined, the external pressure for a cylinder is fixed by this stress and by the thickness of the plate. If we saw-cut this plate on one side, the permissible

COLLAPSES OF CYLINDRICAL FURNACES OF VERTICAL BOILERS.

1643	23	27	2·4	5	3·75	1/2*	40	7·80	6·03	*1/32 in. at fracture is probably only a local weakness.
1643	23	27	2·4	5	3·75	1/2*	65	12·60	6·03	*Steam test sometime previous, where plate may have been thicker.
2020	12 and more	30	2·9	5	4·25	1/2*	42	8·90	5·81	*1/32 in. at fracture is probably only a local weakness.

The pressures in brackets are those to which the safety valves were loaded, but which were not used for estimating the stresses.

stress will not be altered, but, on account of the local reduction of thickness the permissible external pressure will have to be reduced.

A very interesting case, illustrating this point, occurred recently. A furnace had grooved very severely along both sides of the firebars, until the limiting collapsing stress, as determined by the uninjured portion of the plate had been reached, and then the two sides developed two very sharp, long bulges, the upper half of the furnace as a whole settling down about 1½ in. The rigidity of the uninjured portion prevented any general deformation, and the failure was due to a local excess of crushing stress.

The method of dealing with the reported collapses was, therefore, to estimate the actual collapsing stress at the locally reduced section where the final rupture took place, and to compare this with a collapsing stress estimated from the overall thickness of the furnaces as a whole. Here, however, a serious difficulty was encountered, which could easily be obviated in future Board of Trade reports, for in no single instance has the average thickness of the collapsed furnace been measured. The only available information is the original thickness and the thickness at the fracture. There are, unfortunately, a number of reports in which even no mention is made of the fracture thickness, in others the pressure has not been ascertained, and yet in others the collapses were not due to weakness or overpressure as stated in the report, but most probably to overheating. These imperfect reports are not included in Tables III. and IV. As, however, even these reports might be made useful, their number are here given. Incomplete reports: Short furnaces—No 149, 439, 601, 681, 771, 1,081, 1,136, 1,237, 1,297, 1,423; long furnaces—Nos. 58, 230, 326, 346, 362, 538, 547, 619, 791, 808, 864, 871, 1,066, 1,149, 1,601, 1,682, 1,825, 2,295. Overpressure generally due to inoperative safety valves: Short furnaces—Nos. 177, 276, 983, 1,211, 1,246; long furnaces—Nos. 117, 199. Overheating: Short furnace—Nos. 874; long furnaces—Nos. 230, 782, 859. Oval furnaces: Long—Nos. 1,152, 1,208, 1,292.

In the absence of information about the average thicknesses of plates in Tables III. and IV., it seemed at one time hopeless to continue this enquiry, but it was found that as a rule the estimated collapsing pressures for long furnaces, detailed in the upper portion of Table IV., agreed fairly well with the actual collapsing stresses. Now, in these cases the collapsing stress is not materially affected by the average thickness, and it was felt that by making some reasonable assumption as to general wasting in the course of years, the short furnaces in Table I. might also be harmonised with the formula. The first assumption that the average wasting was proportioned to the local corrosions, an assumption which it must be admitted is not generally correct, led to no satisfactory result, but better results were obtained when it was assumed that furnace plates are subjected to an annual loss of thickness. The most concordant results were arrived at on the assumption of a loss of 1-64 in. in five years, or about 1-320 in. per annum. Then, however, it was found that the second term in the expression for the collapsing stress, the term which might be said to take into account the supporting influence of end plates and stiffening rings, was carrying too much weight, and on halving its co-efficient from 13.5 to 6.75 reasonable harmony was established.

Tables III. and IV. have, therefore, been arranged as follows. Column 5 gives the original thickness of the plates in sixteenths of an inch; column 6 gives the thickness as estimated by deducting 1-64 in. for every five years of furnace life; column 9 gives the collapsing pressures as estimated from information about boiler pressure and minimum plate thickness. These details are sometimes not very reliable, and when as in Table III., Nos. 111, 719, 1,512, 1,643, 2,020, thicknesses of 1-32 in. and even of 1-64 in. are reported, one is inclined to assume that the surveyor has fixed on very small local wastings without mentioning the fact. These doubts are confirmed by the fact that in all these cases the apparent collapsing stresses are greater than those estimated by the formula. Column 10 contains the collapsing stresses as estimated by the formula

$$S = 3 + \frac{6.75}{1 + 3\ L^2/t^2}$$

The difference between this formula and the older one is an important one, and makes it appear that in practice short furnaces are weaker than experiments have indicated, and as here it is a question of safety it is advisable, until more reliable information comes to hand, to choose the one which gives the lower results of the two. On the other hand, whereas it is only right that large factors of safety should be used when applying the results of carefully conducted

COLLAPSES AT CYLINDRICAL FURNACES OF LONG BOILERS.

1627	3	32·5	2·4	8	8	2	150	8·75	6·90	Fairly uniform wasting.
2235	13	33	3·5	7	6·25	¼* to 4	55	6·50*	6·37	*1/64in. is evidently very local. Stress estimated on 1/16in.
HAWKSLEY FURNACE.										
1438	20	36	3	6	5	2	43	2·77	6·37	
MARINE-TYPE BOILER.										
378	12	12·5	6·3	5	4·5	3	68*	3·67	3·98	*The safety valve was inoperative.

The pressures in brackets are those to which the safety valves were loaded, but which were not used for estimating the stresses.

laboratory tests to practice with all its unforeseen disturbing influences, comparatively small factors of safety may be employed when practical results, in this case actual explosions, are applied to practice.

Now it appears that the lowest results in Tables III. and IV., neglecting one or two extreme but doubtful cases, are only 30 per cent. lower than the above formulae, and if we reduce it to 70 per cent of its above value we have

$$S = 2 + \frac{4.5}{1 + 3\ L^2/t^2}$$

and we might say that if any furnace which did not comply with this formula had been removed in the past there would have been no collapses from weakness or overpressure during the last 37 years.

It is probable that if fuller information had been available, the conclusion might have been drawn that even higher pressures would not have resulted in collapses, but there is also the possibility that the conclusion might have been in the other direction, and it is, therefore, better, in judging of the safety of a furnace to make a further reduction of say 25 per cent. and then the formula would be

$$S = 1.5 + \frac{3.3}{1 + 3\ L^2/t^2}$$

These formulæ lead to higher working pressures than are at present customary.

The cases reported in Tables III. and IV. almost certainly include a fair number in which, in addition to wastings, the furnaces were weakened by some amount of overheating, due to scale, grease, and mechanical stokers, and it is, therefore, not likely that these influences will have a greater weakening effect than is represented by the formulæ.

One of the objects for which this enquiry was undertaken was to ascertain whether, in the same way as in shell plates, the steel or iron of which furnace plates are made deteriorates on the surface due to corrosive influence. If that were so, then in the long furnaces in which the second, or rigidity factor or the formulæ has practically no influence, the collapsing stresses should fall below three tons per square inch. As will be seen by Table IV. this is not the case, the average collapsing stresses being about three tons, which was the average value found with new experimental furnaces. Evidently, therefore, the old material is as good as the new as regards compression stresses.

It would not be advisable to dismiss this subject without drawing attention to the fact that the empirical formula, which fits the cases under consideration, does not agree with some of the conclusions arrived at by mathematical means.

Thus, if we look on the local wastings dealt with here as if they were longitudinal grooves in the sides of furnaces, it is evident that the line of thrust, which in the uninjured furnaces is a circle which passes through the centre of the furnace plate, will in the grooved furnace pass to one side of the centre of the reduced section and must produce bending stresses. Thus, if a ½ in. plate be reduced on one side by a groove ⅛ in. deep the maximum stress in the reduced section will be 2.67 times the average stress in the ½ in. plate. But this bending stress will tend to bulge the plate a little, thereby increasing the eccentricity and with it the stresses.

It would, therefore, be reasonable to suppose that a locally wasted furnace should be very much weaker than the ratio of the reduced thickness to the original thickness. There can, however, be no doubt that in the collapses here considered this influence is negligible, and need, therefore, not be taken into account.

Then also it can be shown mathematically that in the very long furnaces the resisting powers should vary inversely as the cube of the ratio—thickness divided by diameter. Experiments supporting this view have been made by Carman (University, Illinois; Bul. 1903, Vol. III) and by Stewart (American Society of Mechanical Engineers, 1906), but although this point was borne in mind while analysing the present cases, no indication that this ratio has any influence on the strengths of furnaces could be detected. Possibly another method of attack may confirm these theories, and it is hoped that the data contained in the present tables may be useful for this purpose.

The vexed question of the strength-value of cross tubes in donkey boilers also came under review. Thirty-four reports (see Table V.) contained sufficient details for estimating the collapsing pressures. Cases in which the firebox plates had wasted away to less than 1-16 in. were not included in this summary, which is arranged according to thickness of plates. No collapses were recorded of welded fireboxes, so that it would seem that when, as certainly happens, welded fireboxes give way, they do not as a rule tear. The tables contain particulars of three collapses of steel fireboxes; this is too small a number on which to base a definite conclusion, but it will be seen that for this material the collapsing stresses are below the average, and it is, therefore, not desirable to credit steel fireboxes as be-

1169	—	18, 1, 99	—	2	3	7	42	W. I.	2 laps	—	3/8	150	3·75	Two rows of stays 17½in. apart, 16½in. pitch. Stayed part gave way.

ing stronger than wrought iron ones. There is no indication that the firebox lengths affect the collapsing stresses, the average for fireboxes of 5 ft. to 6 ft. 8 in. being 3.31 tons, which is practically the overall stress for furnaces of from 3 ft. to 4 ft. 6 in.

On comparing the average collapsing stresses of Tables III. and V. we find, for thicknesses of 1-16 in., that they are 5.69 tons for fireboxes without cross tubes, and 3.87 for those with them, the ratio being as 1.0 to 0.68. For thicknesses of from 3-32 in. to 3-16 in. the mean collapsing stresess are respectively 4.15 and 2.98 tons, the ratio being as 1 to 0.72, and the conclusion to be drawn is that fireboxes with cross tubes are from 25 to 30 per cent. weaker than plain ones. In only two collapses had the fireboxes been strengthened with screwed stays. This number is too small for any definite conclusion to be drawn, but the average collapsing stress is 4.15 tons, which is equal to the stress for cylindrical fireboxes of about the same thickness of plate.

The following reports were either incomplete or otherwise unsuitable for incorporation in Table V.: Nos. 101, 172, 549, 606, 965, 1064, 1114, 1232, 1382, 1418, 1474, 1495, 1676, 1767, 1827. Cases of over-pressure: Nos. 88, 108, 145, 189, 219, 223, 336, 363, 468, 516, 685, 853, 860, 1190, 1298, 1553, 1631, 2023.

In the past these experiments have served as a guide in the determination of the safe working stresses for donkey boilers, the usually adopted factor of safety being four to five. No collapses occurred at these working stresses, which would be about 1.0 to 1.25 tons per sq. in. The nearest approaches to them are No. 296, with 1.67 tons, and No. 1,764 with 1.72 tons. Too much importance should not be attached to these isolated cases, more particularly as the No. 296 stress is estimated on the average thickness of the fracture which is across the fibre, and it is not at all probable that the part which first bulged was even thinner than 0.19 in. The collapse of No. 1,764 looks as if it had been a very similar one to No. 296.

From this comparison it will be seen than with regard to vertical boilers with cross tubes engineers have been living in a sort of fool's paradise, but fortunately without serious consequences. They thought that these boilers had a factor of safety at from four to five—actually it was only about two. They will now have to ask themselves the very serious question—a question which cannot be settled here—Should the working pressures of vertical boilers be reduced by about 50 per cent. in order to comply with the custom of allowing a margin of 300 per cent. for unforeseen contigencies, or should this old custom be assailed and a lower factor of safety adopted for other boilers and parts of boilers?

I have on many occasions ventured to call the factor of safety "a measure of our ignorance"—ignorance as to the actual intensity of stresses, ignorance as to the ability of materials to withstand them, ignorance of the working conditions of boilers to which boilers are occasionally subjected. The present enquiry tells us that the sum total of all these ignorances, expressed as it were in terms of donkey boilers, working pressures does not exceed 100 per cent., and the question which will present itself to engineers is—Is our ignorance with regard to shell plates, stays, flat plates, etc., greater, or is it less than our ignorance with regard to a type of boiler which, both as regards accessibility and working conditions, is looked upon as being of the lowest order?

It is hoped that the above investigations into the strengths of some parts of boilers which are a continuation of previous investigation into other parts may prove of service in the near future, when many works may consider it advisable to renew their boilers.

Speaking before the South African Institute of Electrical Engineers, Mr. J. W. Kirkland said that the means of making electricity available for general purposes in the process of railway electrification are not easily to be decided. The minimum voltage for the main transmission line is 100,000 volts. Anyone who knows anything about lightning-arrester protection and switchgear for 100,000 volts will realise that to supply 50 horse-power or 100 horse-power to an adjoining municipality from that voltage is economically impossible. He thus advocated a transmission scheme of three-phase, 50 cycles, at the highest voltage permissible over the mountain peaks, fed at infreqeunt intervals into a low voltage scheme of from 10,000 to 20,000 volts; from that low voltage scheme it would be possible to supply municipalities and private consumers without too great a cost for switchgear and lightning-arrester protection. Automatic sub-stations tapping off the lower tension system would supply the railways.

At the beginning of 1915 the Swedish State Railways equipped fifty ore trucks —self-clearing type—with ball bearings as an experiment. The trucks, according to the *Iron and Coal Trades Review*, were all six wheelers, weighing 11.5 tons and carrying 35 tons, so that the load on each axle at full load was about 15 1-2 tons. In the comparative trials made as to the starting and running resistance with standard and bearings, it was found that with the plain bearings the running resistance was largely dependent on the time during which the trucks had been in motion, the load, and the temperature of the tire. The starting resistance also depended on the same conditions. With ball bearings, however, the running, resistance was quite independent of these external factors, and was 38 per cent. lower than with plain bearings. The starting resistance with ball bearings was not greater than the running resistance, and only a fraction of the starting resistance of trucks with plain bearings. Over four years experience has shown that the length of trains can be increased from 15 to 38 per cent.—according to gradient—where ball bearings are exclusively used. No trouble has been caused through the hot bearings so frequent with ore trains.

TRANSFORMER AND FUEL OIL STORED IN CONCRETE TANKS

During nearly two years' test, three concrete tanks, at the Trafford City Foundry of the Westinghouse Electric and Manufacturing Company, built in the summer of 1918, have proved satisfactory as fuel oil containers. Recently, one of the tanks was used to store transformer oil, and held the light-flash oil as easily as the heavy fuel oil.

Each of the tanks has a diameter of 37 feet with a capacity of 125,000 gallons. Built of reinforced concrete, the tanks have successfully resisted the weather and the little seepage that occurred was easily stopped. Recently the tanks were inspected by a representative of the United States Bureau of Standards, who is making a study of the use of concrete tanks for storing oil.

The tanks have been used to store oil for use in both the foundry and works at East Pittsburgh, Pa., a small pumping station being used to drain oil into cars for shipping. It is thought that as the first tanks have proved so successful other concrete containers will be installed as needed.

NEW USE FOR CO_2

The effect on the growth of plants caused by increasing the amount of carbon dioxide in the atmosphere has been tried in Germany, and the results are said to have been very promising. The gas, obtained in the process of smelting iron ore, was supplied by pipes to an area of some seven acres, and the crops taken off this land were, from 82 per cent. upwards, greater than those from similar, but untreated plots.

Mr. Harvey C. Rose, son of City Treasurer J. O. Rose, has been appointed as resident engineer, with headquarters in Guelph, in connection with the construction of Provincial Highways in Western Ontario. Mr. Rose will have as his section of the highway the road between Guelph and Hespeler, which has been designated as a provincial highway, and the road from Hespeler to Kitchener, by way of Kossuth; also the road from Kitchener to Galt, via Preston, and from Guelph to Puslinch Station, on the Brock road. The road from Guelph to Mount Forest and Owen Sound has also been designated as a provincial highway and some construction work will be done on it this year.

The Pratt and Cady Co., Inc., Hartford, Conn., have a booklet describing the Davis' Hot Water Service Heaters which they will be glad to forward on request to anyone interested.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

HAVING covered in previous articles the groundwork of an arithmetical nature, we propose to take up the actual study of that part of engineering which is essential to the stationary engineer. As the first part of a steam plant to be considered is the boiler, we will start at that end, and take up in turn its functions, design and operation.

Strength of a Sphere

A boiler has at once to be strong enough to contain steam at a high pressure, and as light as possible in construction to offer the least resistance to the transfer of heat through the plates. To meet these requirements, it must be built in the form which is best suited to them. The ideal form would be that of a sphere, but as this is not a practicable shape, most boilers are built to a design which is a compromise between the ideal and the possible. This takes the form of a cylinder with flat or spherical ends, except in special cases, such as a locomotive type, where the firebox is usually of a square section. When flat plates are used in the construction of a boiler, special means of staying them must be introduced.

We have said that the sphere would be the ideal form of construction. Why should a spherical form be better able to resist pressure than any other kind? We will go into the reason for this and make it plain.

If we have a sphere subject to internal pressure, the effect of this pressure tends to tear the sphere apart on a diameter, or on a diametrical plane. We can, therefore, consider the forces as acting on a plane at any diameter. The area of this plane will be $D^2 \times .7854$, and the total pressure will be the pressure per square inch multiplied by the area of the planet or if S=Total stress, then $pd^2 \times .7854 = S$. Resisting this force is a ring of metal whose sectional area is equal to the circumference of the mean diameter of the sphere at the diametrical plane, multiplied by the thickness of the metal. Suppose we have a sphere of 60 inches diameter inside, and 1 inch thick, sustaining an internal pressure of 1 inch thick, sustaining an internal pressure of 100 lbs. per square inch. Then the total stress on any diametrical plane would be

$$100 \times 60 \times 60 \times .7854 = 282744 \text{ lbs.}$$

The metal resisting this stress will have a mean diameter of $60.5 \times 3.1416 \times 1 = 190.06$ sq. inches. If the metal has a tensile strength of 60,000 lbs. per square inch, which is usual for boiler plates,

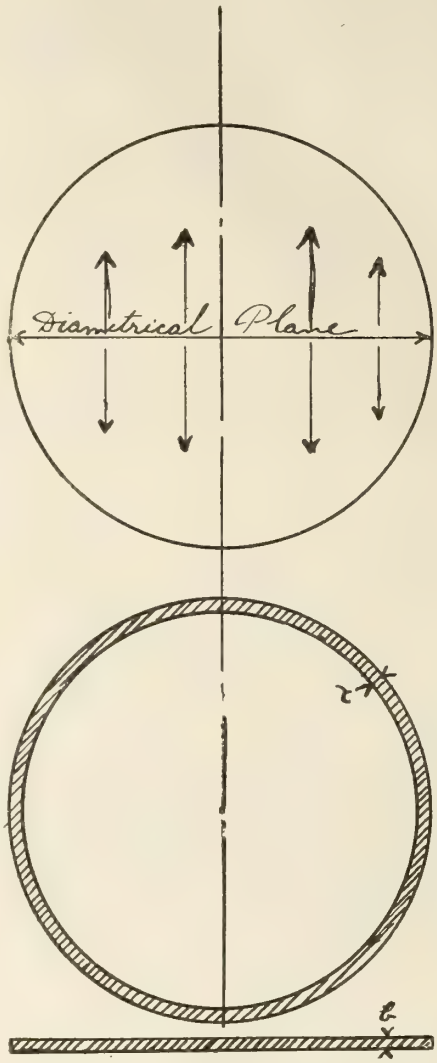

DIAGRAM OF SPHERE.

the breaking stress would be

$$190.06 \times 60{,}000 = 11{,}403{,}600 \text{ lbs.}$$

If we allow a factor of safety of 6, that would give a safe working stress of $11{,}403{,}600 \div 6 = 1{,}900{,}600$. This divided by the area gives $1{,}900{,}600 \div 2{,}827.4 = 672.2$ lbs per square inch, inch, which is considerably higher than the stress it is carrying. Let us take the example another way, and see what thickness of metal would be required to sustain a pressure of 100 lbs. per square inch, the safe allowable stress being 10,000 lbs. per square inch, which is the same as before. We have

$$pd^2 \times .7854 \times 100 = \text{Total stress}$$

and $3.1416d \times t \times 10{,}000 = \text{Resistance.}$

These two must be equal, that is the resistance must equal the stress. We know every factor except the thickness, and this we must find. To do this we equate the two quantities thus

$$3.1416d \times t \times 10{,}000 = pd^2 \times .7854$$

Substituting the figures we have

$$3.1416 \times 60 \times t \times 10000 = 100 \times 60 \times 60 \times .7854$$

Then to find t we must divide the known quantities on one side of the equation by the known quantities on the other, and the sum becomes

$$t = \frac{100 \times 60 \times 60 \times .7854}{3.1416 \times 60 \times 10000}$$

Cancelling out, as we learnt to do when studying fractions we have

$$t = \frac{3}{20} \text{ or } .15 \text{ inches}$$

which is roughly 1/6 of the thickness we originally took.

As we have noted, it is not practicable to make a boiler of the spherical form, and the introduction of the flat ends introduces a longitudinal stress as well as the bursting, or circumferential stress. However, this stress is only half of the circumferential stress, as we will show immediately. Incidentally, this will prove the reason for the comparatively light construction of the circumferential joints in a boiler to that of the longitudinal ones.

Taking our sphere again, imagine a ring of metal which is a section of the sphere at a diameter. Imagine it to have an internal diameter d, a thickness t, and a breadth b. Let p= internal press and f the stress induced by that pressure. Then the total force tending to rupture the ring will be $p \times d \times b$. The resistance to this stress furnished by the metal in the ring will then be $2t \times b \times f$. Now as the resistance equals the bursting stress we have

$$p \times d \times b = 2t \times b \times f.$$

The stress f then tending to burst the ring will be $f = \frac{p \times d \times b}{2t \times b}$. The b on top and bottom cancel out, and we have

$$f = \frac{pd}{2t}$$

Now the stress on the end of the boiler tending to tear it apart longitudinally may be called f_1. This force will be represented by the product of the pressure per square in. on the area or $pd^2 \times .7854$. The metal resisting this will be a ring whose section is $3.1416d \times t$. The resistance offered will be $3{,}1416 \times t \times f_1$. Then f_1 will be

$$f_1 = \frac{d^2 \times .7854 \times p}{3.1416d \times t}$$

Cancelling out we get $f_1 = \frac{dp}{4t}$. As $f = \frac{dp}{2t}$ we see that the stress f_1 is equal to only half of f.

The above calculations show the stresses that would be put upon a hollow metal sphere, or a cylinder with flat ends, formed of solid sheets. No boiler is formed in that way, because the sheets have to be joined together by rivetting in various fashions, which introduce weaknesses as compared with a solid plate. The flat plates have to be stayed, and furthermore are weakened by being bored for the reception of tubes. The shells and heads are pierced for pipe openings and manhole openings, and where this occurs, some method of reinforcing must be resorted to. All these factors have to be reckoned with in the design of a boiler, and they necessarily introduce a large number of calculations. These are all made by means of standard formulae, but it is not our intention to merely work out examples on these. The engineer should know something of the principles on which these formulae are founded, and we will as far as possible, explain these principles first. In order to do this, we will take up the design of a boiler according to the Ontario rules, and work it through from beginning to end. The reader will thus gain a clearer conception than by the mere working out of formulae.

Some Definitions

There are some terms used so frequently that it is well to have a clear understanding of their meaning before we go too far. Some of them we have used already in this article, such as tensile stress, safe working stress, factor of safety. Shearing and compressive stress, elastic limit, etc., are others, which we will define at once.

Stress.—When a material is subjected to a force, internal or external, which tends to cause distortion, it is said to be subject to a stress.

Strain.—If a material, which is subjected to a stress, alters its form as a result, the amount of alteration is called the strain. In other words, stress is the cause and strain the effect. These two terms are often confused and loosely used even by those who know better.

Ultimate Strength. — The ultimate strength of a material is the highest resistance it offers to rupture, either by shear compression or tension. The ultimate strength therefore corresponds to the breaking stress

Factor of Safety.—The factor of safety is a factor by which the ultimate strength or breaking stress is divided in order to obtain the safe working stress. It is a variable factor depending on the material, workmanship, nature of the duty to be done, etc. In boiler practice it ranges from 4.5 to 6. Factors of safety for different materials have been found empirically and are applied according to the results of experience.

Thus, in the case of a bridge subjected to live loads of varying intensity, a factor as high as 10 or 12 may be used. For a beam carrying a fixed load not subject to shock or variation, the factor may be 4. The object of the factor of safety is of course to allow a margin to take care of unexpected shocks and stresses which cannot be allowed for in calculations.

Tensile Stress.—A stress applied to a material, which tends to extend it longitudinally is called a tensile stress. The resistance which the material offers to this stress is its tensile strength.

Compressive Stress.—A stress which tends to close the molecules of the metal together, or in other words to shorten a bar, is called a compressive stress. The resistance offered by the metal is the compressive strength.

Shearing Stress. — A stress which tends to make one part of the material slide over the other part is a shearing stress. Opposed to this is the resistance or shearing strength of the metal.

Torsional Stress.—Torsional stress is a twisting stress such as that applied to a bolt by the tightening of the nut. It is really composed of shearing and tensile stress in combination.

Elastic Limit.—This is a term which is very much used in connection with boiler problems and should be understood by every engineer. When a metal is subjected to a tensile stress it tends to elongate. When the load is removed the material returns to its original form. This is true up to a certain point, after reaching which it fails to return but retains a permanent set or distortion. This point is called the limit of elasticity or elastic limit. After this is reached any further pull will result in a "fielding" of the material, which is not in proportion to the stress, until final rupture takes place. Up to the elastic limit the elongation is in proportion to the load applied. This point occurs usually at about one-half the ultimate strength of the material.

Modulus of Elasticity.—This is the relation that exists between stress and strain, and may be expressed, if E = Modulus of elasticity, then

$$E = \frac{\text{Stress}}{\text{Strain}} = \frac{\text{Stress for sq. in. section}}{\text{Elongation in one inch}}$$

Kent's Pocket Book gives the definition as the load per unit of section divided by the extension per unit of length, which is as above. Thus, if a stress of 60,000 pounds per square inch produces a strain of .02 inches in a piece 10 inches long, the strain per inch will be .002. Then E will be

$$\frac{60{,}000}{.002} = 30{,}000{,}000.$$

Conversely we can find the strain if we know E, and the stress, or we can find the stress if we know E and the strain.

Thus if E = 30,000,000, and strain = .002, then stress will be

Stress = E × strain.

Stress = 30,000,000 × .002 = 60,000.

If we know E and stress we find strain by

$$\text{Strain} = \frac{\text{Stress}}{E} = \frac{60{,}000}{30{,}000{,}000} = .002$$

If we call the strain = S, stress = f, and modulus = E. Then we have

$$E = \frac{f}{s}$$

$$f = E \times s.$$

$$s = \frac{f}{E}$$

HERE IS ANOTHER MIRACLE

Copper is a red metal and if mixed with tin or zinc it imparts color to them according to the proportion in which it is mixed. For instance two pounds of copper and one pound of zinc makes yellow brass, while copper and tin mixtures make a red bronze of a lighter color than pure copper. But if one pound of manganese is mixed with five pounds of copper the alloy is pure white. Where did the red go? And equally as strange, if the manganese is removed the red comes back, where did it come from? One pound of nickel mixed with four pounds of copper will bleach it to a pure white, being, not quite so powerful as bleaching agent as the manganese.

In a lecture recently delivered before the Institution of Civil Engineers in London, England, Sir Dugald Clerk revived an interesting proposal made by the late Lord Kelvin for the heating of rooms. This proposal is not easy to explain without diving into mathematics and the abstruse laws of heat, but it may be expressed as a process of using an engine to extract some of the heat from the cold air outside a room and adding it to the heat of the air inside the room. The curious and puzzling thing about this process is that the heat so added is, under certain conditions, much greater than the heat equivalent of the work done by the engine. In theory, therefore, an electric motor may be used very efficiently to warm a room. Whether the notion will work out satisfactorily in practice remains to be seen, but in view of the ever-increasing cost of fuel this fascinating problem is likely

We have received an interesting booklet illustrating the Moore Steam Turbines, made by the Moore Steam Turbine Corporation, Wellsville, New York, U.S.A. This is numbered Bulletin 24. It gives a general description of single and multi-stage turbines, as manufactured by the firm, and also clear descriptions of the details of construction. In connection with the turbines, reduction gears are also supplied. Several illustrations of typical applications of the units are shown.

The Brush Pilot Gauge Company, of Springfield, Mass., are now making plug gauges with a brush attachment on the nose, that cleans out the hole before the gauge enters, thereby minimizing the wear and assuring greater accuracy in gauging.

The Theory and Practice of Electricity

In These Articles the Theory Will be Developed Sufficiently to Enable the Practical Man to Grasp the Underlying Principles of Apparatus Under His Care, Both Direct Current and Alternating

W. F. SUTHERLAND

IN the last lesson various types of electrical circuits were taken up and Ohm's law was discussed. In this present issue, it will be well to discuss at some length various applications of Ohm's law in the proportioning of feeders, wiring, etc. Before doing so a knowledge of the various materals used and their properties may not be out of place.

Some materials conduct electricity better than others, just as some materials are more suitable for insulating purposes than others. Silver is the best conductor and would be ideal for the purpose if it were not so expensive. Copper is next and is the metal most in commercial use to-day. Gold is next in order, but of course is too expensive. Next to it is aluminum, and in copper and aluminum we find the most suitable metals for transmission lines and electrical apparatus. The choice between the two is governed by their relative cost in conjunction with the weights of each necessary, and by their mechanical characteristics as well as by the space available.

Aluminum has found considerable use on high tension line work and the aluminum cable is often reinforced by a central steel wire for mechanical strength. It should be mentioned that while aluminum is a much inferior conductor to copper, its lighter weight renders it just as economical and in some cases cheaper by the pound, depending upon the relative prices of the two metals.

During the war zinc was quite commonly used in Germany, not only for electrical wiring, but also for equipment of various kinds. Iron wire is used very commonly for telegraph and formerly to a large extent for telephone circuits. In this case its current carrying capacity is not of so much importance, and its cheapness is of every material advantage.

The following table gives the relative resistance of some of the metals in the order of their conductivity.

Copper is taken as equal to	100
Silver	92.5
Copper (annealed)	97.5
Copper (Matthiessens standard)	100.0
Aluminum (99 per cent. pure)	161
Zinc (pure)	362
Iron (very pure)	570
Lead	1280

Wire Gauges

The commercial wire in use to-day is made in a number of varying sizes and in this Country and the United States according to what is known as the B & S. (Brown and Sharpe) wire gauge. In this gauge the sizes of the wires bear a very definite numerical relation to one another. Many other gauges have been in common use but are being rapidly superceded, and one of the largest electrical manufacturing companies has even discarded the use of gauge numbers entirely, calling every size wire by its decimal equivelant or by its area in circular mills.

The B & S. gauge is based on a series of sizes such that if the diameter of one size is multiplied by the number 1.084, the diameter of the next size larger will be given. This property is valuable in some respects for it enables one to determine approximately the characteristics of various sized wires when those of one are known. The area of any wire whose gauge number is known when multiplied by 1.261 will give the area of the next size larger, and the area of any wire whose gauge number is known, multiplied by 2 will give almost exactly the area of the third size larger.

No. 10, B. & S. gauge copper wire which is about one-tenth inch in diameter (101.9 mills) has a resistance of about one ohm per 1,000 ft., and this fortunate coincidence is a useful thing to remember.

Mills and Circular Mills

The mill has been used above in speaking of wire diameters and it simply means the one-thousandth part of the inch. For instance, we might have a wire 571 mills in diameter, this would be equal to 571-thousandths of an inch, or .571 inches.

In ordinary life the area of a circle is found by squaring the radius and multiplying by 3.1417. It can also be found by squaring the diameter, multiplying by 3.1417, and dividing by four. This gives the true measure of the area, but the electrical engineer, through sheet inherent laziness, perhaps, or because of its greater convenience, has adopted another measure of area—the circular mill, this is simply the area in mills squared. It does not give the true area, but this is of little importance when resistances of other characteristics are given in terms of circular mills since the result will be correct. In the table given herewith the values for the area of wires in circular mills have been rounded off to even figures.

Carrying Capacity of Wires

When an electric current is sent through wire the resistance causes a certain voltage drop, and a consequent loss of power. This power lost is equal to the voltage drop multiplied by the current carried in amperes, and is expressed in watts, the formula expressing this relationship is

$$W = E\ I.$$

If we know the resistance of the wire and the current carried we can also easily determine the power lost since

$$E = I\ R.$$

Where E equals the pressure drop in volts I, the current carried and R, the resistance. If this expression is substituted in equation, $W = E\ I$, it becomes

$$W = I\ R \times I, \text{ or } W = I^2R.$$

The energy thus lost is created into heat and in heaters, etc., does useful work, or in the case of wires carrying current to motors, etc., is lost. The heat generated plays an important part in the proper selection of any given wire size, and rules have been adopted by various organizations to limit the current carrying capacity to such values as will be safe for insulation. The last two columns in the table give the National Electric code standard, and it will be noticed that a difference exists between the values given for rubber-covered and weather-proof insulation. The weather-proof wire can safely stand a higher temperature than the rubber-covered, and so is allowed a greater carrying capacity.

In designing a line for any given work, whether it be running of motors or the lighting of a building, two factors have to be taken into consideration, the current carrying capacity of the line and the voltage drop in the distance transmitted. On extremely short circuits the current carrying capacity will govern, since comparatively little resistance is introduced, while on longer circuits the voltage drop will control. For instance it may be of interest to find out what wire will be required to carry current to a 50-horse-power motor (direct current), at a voltage of 550.

In the first instance let us suppose that we have a line 100 ft. long. The amount of electrical energy required will be $50 \times .746 = 37.3$ kilowatts (since 1 h.p. = .746 kilowatt). At 550 volts the current carried will be neglecting friction losses, etc. $37.3 \times 100 \div 550 = 61$ amperes. Consulting the table we see that for a current of 61 amperes we will require a wire, a No. 5 wire in rubber-covered or a No. 7 weather-proof. Since odd sizes are sometimes hard to get, and in the smaller sizes are not sold, it would be well to use either No. 4 or No. 6, depending on the insulation. If No. 6 were used, 200 ft. of it would have a resistance of $0.3872 \div 1000 \times 200 = 0.07745$ Ohms, (from table). At 61 amperes this would give us a voltage drop of $0.7745 \times 61 = 4.75$ volts, or .86 per cent. which is negligble.

Let us now take the same motor and calculate the size wire required if it were 5000 ft. away. In the first place we must come to a decision as to what

TABLE 1—PROPERTIES OF COPPER WIRE.

per centage of the power we can afford to waste, and just what voltage we can afford to loose. While wiring formula are given in which the capital cost figures and which are necessary for large installations, we will assume that a voltage drop of about 5 per cent will be about right.

Five per cent. of 550 volts = 27.5 volts.

The amperes carried are the same as before and remembering Ohm's law we can readily determine the resistance of the wire which will give this figure.

$$R. = E. \div I.$$

substituting

R. = 27.5 (the voltage drop) ÷ 61 = .45 Ohms. The total length of wire equals 10,000 ft., and the resistance per 1000 ft. will therefore be .45 ÷ 10,000 × 1,000 = .045 Ohms. This would require about a number 00000 wire, and its current carrying capacity would be more than ample. By allowing double the voltage drop or 10 per cent. we can cut the size of wire down to No. 0.

By doing so we would cut the cost of the transmission line down considerably, but we would be payng considerably more for power.

The first table given in this issue takes in wire only up to No. 0000 size. Above this size conductors are usually rated in circular mills, and are usually supplied stranded for ease in manufacture and for greater flexbility.

Table two gives corresponding data concerning conductors over four nought in size.

TABLE 2—PROPERTIES OF COPPER CABLE.

Area in Circular Mills	Approx. dia. over copper in fractions of an inch	Ohms, at 1,000 ft. at 59° F.	Carrying Capacity Amperes Rubber covered	Carrying Capacity Amperes Weather-proof.

Resistance and Temperature

The resistance of a conductor is not constant with varying temperatures. The resistance of metallic conductors increases with the temperature rise, while that of carbon decreases. A peculiar fact is also noticeable in the behavior of what we commonly take to be insulators, when they are at a red heat or above, for many substances, perfectly satisfactory insulators when cold conduct electricity quite noticeably when hot. Firebrick, magnesite brick, the refractory filament of the old Nerust lamps are all examples of this type of insulator.

The resistance of metals decreases rapidly when they are cooled to very low temperatures. At—273 degrees centigrade, if it were possble to reach it, the resistance would probably vanish. A scientist in Holland has succeeded in producing extremely low temperatures approaching this point and has found that a current of electricity will circulate for days in a circle of lead wire and that is very large in amount.

Any change in resistance is due to the temperature alone, and is not dependent upon whether the change in temperature has been caused by current flowing or not. Ordinary, simple metal conductors, such as copper, tin, aluminum, zinc, etc., change resistance about 4-10 per cent per degree centigrade change in temperature while alloys in general and certain alloys in particular change in resistance much less than this. Iron changes in resistance most of all, altering 6-10 per cent. per degree.

Canadian Plant.—A new factory is being erected by the Coleman Lamp Company of Wichita, Kansas, at the corner of Queen East and Don roadway, for the manufacture of all kinds of portable lamps.

Editor, Power House.

Dear Sir:

What pressure can be carried on a boiler stay, the plate being 7/16 and the pitch 9x9 inches?

What is the rule when stays are diagonal?

ANSWER.—For stays supporting the flat surface of a boiler head, if stays are of steel unwelded, a tensile strength of 8,000 lbs. per square inch can be allowed. You give the pitch of stays as 9 in. x 9 in.=81 square inches supported by one stay. As you do not give size of stay we must assume it. Suppose we have stays of 1½ in. diameter, the area would be 1.5 x 1.5 x .7854=1.767 square inches. The stay would then be able to support a total pressure of 8,000 x 1.76=14,080 lbs. As the area to be supported is 81 square inches the pressure allowed would be 173.8 lbs.

If you want to find the size of stay for a given pressure, say 100 lbs. per square inch take the area supported multiplied by the pressure which gives total pressure, and divide by the allowable stress on stay 7000, which gives area of stay. To find diameter divide by .7854 and take square root. The formula would be:

where S=Surface supported
P=Pressure per square inch
F=Allowable stress on stay
A=Area of stay.

$$\frac{S \times P}{F} = A. \qquad \text{Diameter} = \sqrt{\frac{A}{.7854}}$$

To find pressure when area of stay is given:

$$P = \frac{A \times F}{S}$$

The method of finding stress on a diagonal stay is as follows: Find allowable stress on direct stay, and multiply it by the length of direct stay divided by length of diagonal stay. The length of the diagonal stay can be found by the rule for the hypotenuse of a right angled triangle which is square of base+square of side=square of hypotenuse. We have then $42^2+14^2=1960$ $\sqrt{1960}=44.2$. Then if the direct stay can carry 100 lbs. the diagonal can carry $100 \times \frac{42}{44.2}$

If the diameter of the direct stay is 1 in. then its area is .7854 and the area of the diagonal stay must be

$$.7854 \times \frac{44.28}{42} = .8288$$

and the diameter would then be 1.026 inches.

The rule for staying flat plates taking the thickness of plate into account is:

$$\frac{C\,(T+1)^2}{S-6} \text{ working pressure.}$$

Where C is a constant which varies according to type of stay and workmanship. T=thickness of plate in 16ths. S=surface supported by 1 stay. C varies from 120 to 200.

The Late W. L. McGhie

THE late Mr. W. C. McGhie, chairman of the Board of Stationary Engineers since its inception, passed away at his home at 58 Asquith avenue, Toronto, on July 9th. Mr. McGhie was widely known and well liked by the engineers of his province, and his passing will be deeply regretted by them. He was a comparatively young man, being only 51 years old.

Mr. McGhie was born in Peel County, where he received his early education at the public school. From thence he went to the Parkdale Collegiate, Toronto, where he finished his educational studies.

He started his career as a stationary engineer in the employ of Mathew Brothers, picture frame makers. He went from there to the Toronto Street Railway, which he left for the Kemp Manufacturing Co. From thence he went to the Rolf Clarke Co. In 1908 he was appointed chairman of the Board of Stationary Engineers, which position he retained up to the time of his death. During his incumbency he was largely responsible for the drawing up of the Stationary Engineers' Act.

Mr. McGhie was a past president of the Canadian Association of Stationary Engineers, a member of the Universal Craftsmen's Council No. 27, Toronto, and a member of the Alpha Lodge, A.F. & A.M.

He is survived by his widow, who was a daughter of the late J. C. Shear, J.P., and a family of five, four daughters and one son.

We understand that nothing has yet been done in the matter of appointing a successor to Mr. McGhie.

Changes in the Act

AN Order-in-Council has been made, authorizing some important changes in the act regarding stationary engineers' certificates. The third class certificate will now allow its holder to operate a plant up to 200 Boiler Horse Power, instead of 150 B.H.P. as formerly. The second class certificate will authorise the possessor to operate a plant of 600 B.H.P. instead of 300 B.H.P., or just double. This amounts to practically making the second class certificate cover most of the plants in Ontario, the number possessing over 600 Boiler Horse Power being limited. The size of plant that can be operated by a man already in charge of it, irrespective of his grading, is also raised to 200 B.H.P., instead of 150 B.H.P. These changes should be welcomed by the stationary engineer, as they would appear to make things easier for them. One result, we imagine, will be a lessening of the number of candidates for a first class certificate. It is hardly to be expected that many men will go to the trouble and expense of obtaining the highest grade certificate if the next lower one will serve their purpose. The change will also be welcomed by owners of plants, as it will save changes of personnel being made, that otherwise might have been necessary.

E. J. Dodd, writing from London, says: At the Canadian Exhibition the MacLean business and technical newspapers and magazines and The Financial Post were displayed at the stand of the Department of Overseas Trade and that quite a number of copies were sold, mainly to persons interested in buying from Canada. One of these was a member of the staff of the Russian Bolsheviki Trade Ambassador, M. Krassin, who made special enquiries and asked if he might be allowed to follow up the reading of the papers by a call on the MacLean Newspapers' London Office. It is difficult to know just what is going to happen in Russia, but one thing is certain, Russia cannot get on a normal producing basis without machinery plant and industrial brains. The Jews who are controlling Russia know this and there are bound to be developments favorable to Canada.

UNITED STATES operated its railroads for twenty-six months, and now the national pastime in that country is figuring out what it cost. It used to be a popular fallacy that running railroads was an easy way to make money, but in these twenty-six months the United States Government owns up to a loss of $715,000,000. One thing the Government was particularly capable at was hanging on new employees, for at the end of the twenty-six months the pay-day casualty list showed an increase of 244,510 recruits, bringing the number from 1,647,097 in 1916, to 1,891,607 in 1919. And on top of this the railroad unions prepare to get wage increases that will add $1,100,000,000 to operating expenses.

THOSE who are engaged in the controversy about building or taking over transportation lines in Ontario for the purpose of electrification, should think seriously and well about the changing aspect of transportation. It is folly to overlook the coming of the truck, as well as the passenger car. Banks are recognizing this in many places, and are financing the making of trucks and tractors, but not passenger cars. When well-built highways are put through the country, and the use of trucks is made possible and profitable, there is bound to be a falling-off in the call for electric or steam road service. The form of locomotion that will take the load from the barn direct to the city market is by all odds the most desirable, as the start, the route and the terminal are all capable of being adjusted to the convenience of the truck owner.

Gas Production vs. Electrical Generation

A VERY lively interest has been shown during the past year or so, in the proposed establishment of super-power stations for the generation of electricity from steam. In England, where the coal situation has been acute, this proposal has been seriously considered, and the question of its advantages from a conservation view point much mooted. The gas industry which is a very well developed one in Great Britain, disputed the claims of the electrical engineers, as to the thermal efficiency of power generation from these stations. Sir Dugald Clerk, the leading authority on gas production and gas engineering in the United Kingdom, and one of the outstanding men in the world in that line, read a paper before the Royal Society of Arts, giving some highly interesting and illuminating figures, which are not without some appeal to Canadian readers.

First of all, Sir Dugald points out that if the present rate of mining, and the increase in that rate keeps on as it is doing, the coal supply of Great Britain will be denuded in less than 200 years. He shows that without coal Great Britain could no longer support a population such as she has at the present day, but would probably be able to support a population of about 20,000,000, or about the same as she had in 1830. In order then, that this great change from a manufacturing to an almost entirely agricultural nation, which would be attended with great suffering, might be postponed as long as possible, coal conservation becomes a very real necessity. The work of the nation must be done with the least possible consumption of coal, and every atom of usefulness must be recovered from each pound of coal burned. Sir Dugald then gives figures showing the thermal efficiency of a pound of coal burned under a boiler to produce electrical energy, and that of a pound of coal carbonised in a gas retort to make gas.

In the United Kingdom about 20,000,000 tons of coal are carbonized annually, the average heat value per lb. being 13,000 B.T.U. The average thermal efficiency is 71 per cent. That means that in order to evolve gas, coke, and tar, 29% of the heat value is lost. Of the remaining 71%, 25% is available in the form of coal gas, and 46% in the coke and tar. The principal product is gas, and if the total heat loss is charged to the gas, then $29 + 25 = 54$ units are required per ton of coal to produce 25 units in the form of gas. Then the thermal efficiency of the gas-making process is $\frac{25}{54} = .46$ or 46%. Of the 20,000,000 tons consumed, the amount required to produce the heat value of the gas generated would be 5,000,000 tons. As the gas is generated with an effiiciency of 46% it requires actually 10.9 million tons. There is still remaining in the coke and tar products the heat equivalent of 9.1 million tons.

The electrical generating stations of the country, using coal with a heat valve of 11,600 B.T.U. consumed 7.3 million tons, and the thermal efficiency of generation was 8.5 per cent. If the coal had been of the same thermal value as that used for gas, the amount used would have been 6.5 million tons. The heat available from the electricity generated being 8.5 per cent. of the heat value of the coal consumed, shows that this heat could have been obtained by the combustion of a little over half a million tons.

The meaning of these figures is this. One ton of coal burned to coke, tar, and coal gas, makes available for power purposes nine times more energy than the same ton of coal burned under a boiler to generate electricity. The paper goes on to show that in the application of this heat by the consumer, gas has an advantage over electricity in many cases. For instance in heating rooms, 100 heat units at the gas works give 27 heat units in the consumer's house. One hundred heat units in the electric generating station on the other hand gives only 3.8 units at the consumer's premises. For cooking, gas applying 3.4 heat units at the oven requires 100 heat units at the gas works, while 100 heat units at the generating station only delivers 1.6 units at the oven. Comparing the performance of the best gas works and electrical generating stations the gas engine gives 13.6 per cent. thermal efficiency, as against 10.4 per cent. for the electric stations. In only the illuminating field does the use of electricity over gas show a gain.

Of course there are many other factors besides thermal efficiency which determine the use of electricity for distribution. Sir Dugald points out that in their own works electric cranes, etc., are in use. The point he wishes to make, and seems to have done so quite successfully, is that the super-power station, generating electricity which is to be supplied to a large radius, is not the best means of coal conservation.

The figures here given should be of interest to many consumers in Canada, where we have vast deposits of coal suitable for gasification, and where we waste coal daily with the utmost cheerfulness.

The paper is printed in pamphlet form, and entitled, "Distribution of Heat, Light and Motive Power by Gas and Electricity," and is crammed full of interesting data.

Progress in New Equipment

THE JONES UNDER-FEED MECHANICAL STOKER

To anyone interested in the economical and efficient burning of coal with the utmost conservation of labor, the mechanical stoking of boilers and furnaces is a subject that will prove both interesting and profitable.

Recently the greatly increased price of coal, the difficulty of securing it at any price, and the scarcity of labor, have combined to offer a wonderful opportunity for mechanical stoker plants to prove their worth, and they have met this opportunity with a remarkable showing.

A new stoker in the Canadian field is the Jones Automatic-Cleaning ("A-C") Under Feed Stoker, manufactured in Canada by the Under-Feed Stoker Company, of Canada, 81 Victoria St., Toronto, formerly the Jones Under-Feed Stoker Co. It is claimed that this stoker will effect a guaranteed fuel saving of at least ten per cent; it will greatly reduce the labor required, it will absolutely prevent smoke owing to the complete and efficient combustion of the fuel, and it will adequately take care of heavy overload conditions due to high peak-loads which are impossible with hand firing. These various economies result in such a saving that the stoker equipment soon "pays for itself—then pays dividends."

Under-Feed Principle of Combustion

Most steaming coals have a high volatile content that is distilled by the heat encountered in the furnace. To obtain proper combustion these volatile gases must be properly mixed with air and burned at a high temperature almost the moment they are released. Under-feed stoking is the only way this can be accomplished efficiently. The operation of the Jones "A-C" Stoker requires every particle of coal and every particle of gas to pass through the incandescent zone, or zone of intense heat. Air under pressure is admitted through the tuyere openeings just below this zone, necessitating complete and efficient combustion of the coal and volatile gases.

Operation

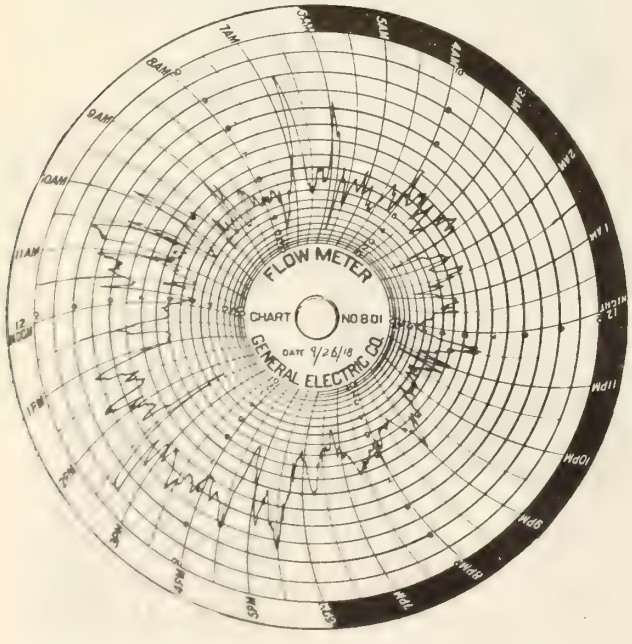
The coal hopper is located directly in front of the stoker. Coal is fed into this hopper either by hand or by gravity from the storage bins. A steam cylinder is mounted immediately below the hopper and in front of each retort, and a ram is connected to the piston of this cylinder. When steam is admitted into the cylinder through the automatic control valves, this ram is drawn outward and a charge of coal falls into the ram case. The automatic control valve reverses the stroke and the charge is forced into the retort, or coal magazine. A rod is connected to the ram and travels through the front end of the retort below the ram with each operation of the steam piston. On this rod inside the retort are bolted two pusher blocks so that the coal is carried upward and rearward with each stroke of the ram.

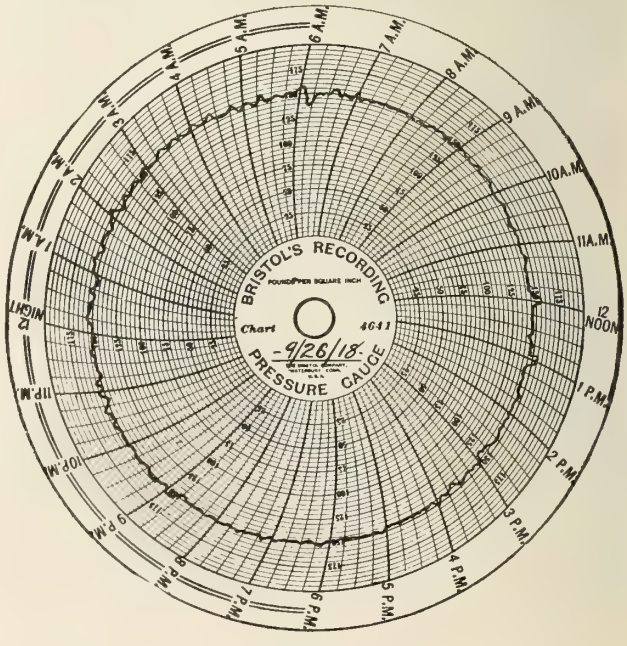
No moving part is exposed to the fire and the only movement is the straight quick thrust of the ram and pusher blocks buried deep under green coal, a condition that insures continuous operation and removes the liability of shut down. The upward and rearward travel of the coal caused by the positive thrust of the ram, insures a continuous breaking-up and automatic slicing of the fire as well as thorough mixing of air and gases.

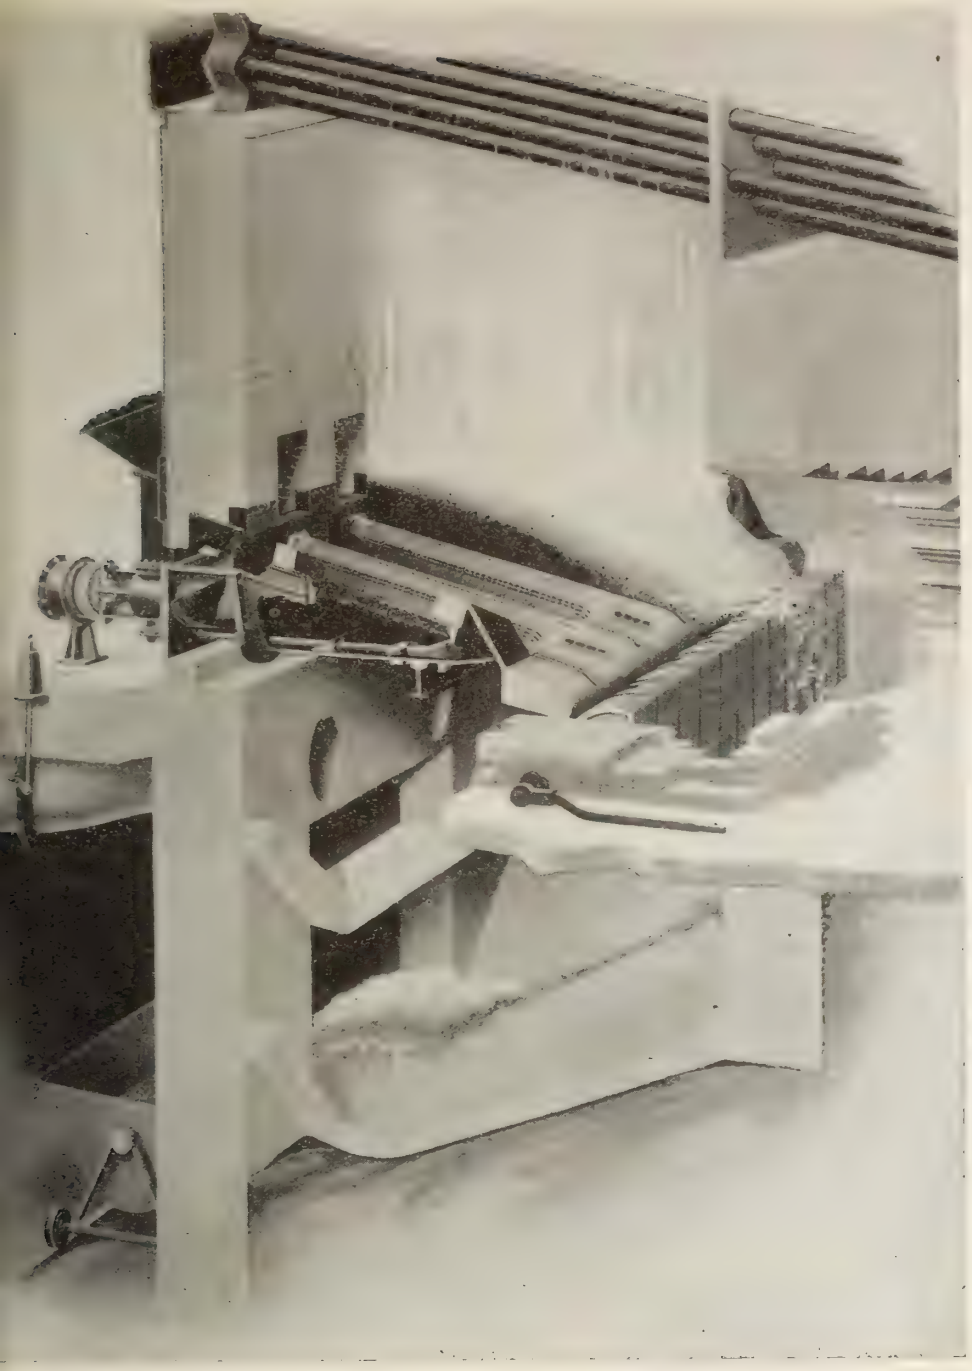
Automatic Cleaning

The intermittent breaking up and ram and pusher blocks previously explained, carries the whole fuel bed slowly toward the rear. Before the fuel bed reaches the dump plate at the rear, the coal is entirely burned and there is nothing left but dead ash. This gradual movement of the fuel bed keeps the fire clean of all ash and refuse. Dropping the balanced dump plate drops the ashes into the sealed ash pit below. This operation is necessary only at occasional intervals and is simple and easy to perform.

Particular emphasis should be placed on the fact that the gradual movement of the fuel bed toward the dump plate is not a gravity movement. The slope of the retorts is not sufficient to cause the ash and refuse to slide or roll tow-







ard the dump plate. It is impossible for the coal to avalanche.

Prevention of Clinker

The intermittent and breaking up and rearward movement of the fuel bed caused by the quick, positive action of the steam ram and pusher blocks prevent the formation of large clinkers. This is done very successfully as shown by actual test. An analysis of the ash show a negligible amount of combustible.

Due to their design, the side tuyeres prevent the formation of clinker on the side walls, by keeping the bed of fuel away from the walls for a considerable height above the top of the retort. Also, due to the air circulation, no clinkers adhere to these tuyeres. There are no clinker formations on the bridge wall because the fuel is practically all consumed by the time it reaches the dump plate.

Fuel Economy

The highest fuel economy is obtained in any stoker when the correct amount of air is supplied to completely burn the coal. Too much air cools the boiler heating surfaces and necessitates the burning of more coal. Too little air does not furnish sufficient oxygen for complete combustion and all available heat of the fuel is not utilized. A low percentage of C02 in the flue gases indicates too much air. A high percentage of CO indicates too much air. Independent adjustments of the fuel and air controls, as exclusively featured on the Jones Under-Feed Stokers, are therefore absolutely necessary to obtain the maximum fuel economy. For this reason cheap coals are burned satisfactorily with the Jones "A-C" Stoker.

Automatic Control of Fuel and Air

The steam pressure itself automatically controls the air supplied to the fire through the tuyeres and also the coal supplied to the retorts. Should the steam pressure drop slightly, both the air pressure and coal supply are increased. If the steam pressure goes up, the air pressure and coal supply are decreased in proportion.

The controlling valve is an important and distinctive feature of all Jones Under-Feed Stokers. It is installed on the steam line to the stoker cylinder and has eight rates of operation. This permits of any desired speed of coal feed for the battery of stokers. Moreover, any retort of the battery may be operated at a different rate from any other retort—a highly valuable feature since it gives absolute control of the fire.

The length and stroke of the pusher blocks may be adjusted to meet any fuel condition encountered by the adjustment of a pin on the connecting bars below the ram outside the furnace. The pusher blocks may also be set as different points on the pusher road. These adjustments permit any desired rate of speed and thickness of fuel bed.

Fires are easily banked, and held any length of time, by feeding in a supply of coal with the ram and shutting off the air and steam supply to the stoker.

Even Steam Pressure

The automatic air and fuel controls of the Jones "A-C" Stoker are so immediately responsive to changes in the steam load, that an even steam pressure is maintained at all times, regardless of variations in the steam consumption.

The flow meter chart and the pressure gauge chart as shown were taken simultaneously at the plant of the Michigan Limestone & Chemical Company, Rogers City, Michigan. The sudden changes in the load, as shown on the flow meter chart at 6.45 a.m., and 2.30 p.m., are not marked by perceptible changes in the pressure, as shown on the pressure gauge chart. The pressure is held very close to 150 pounds at all times over the 24-hour period, regardless of the wide variations shown on the flow meter chart.

Flexibility and Capacity

Extreme flexibility is afforded due to the wide range of operation of the coal and air supply. The shape and size of the retorts are such that a maximum supply of coal may be fed into the furnace when necessary. This is also accomplished by the controlling valve should it be desired for any reason to suddenly "boost" any particular retort. The tuyere openings are so designed and arranged that an abundant supply of air is supplied to burn the coal. The air distribution system below the retorts is well balanced and capable of wide adjustment. These are the reasons for the large coal-burning capacity per square

foot of furnace area. This flexibility and coal-burning capacity are of extreme importance in plants where there is a wide variation in load, or where heavy overloads are frequently required.

Smoke Prevention

Where there is complete combustion there is no smoke, and with this stoker you have complete combustion.

Accessibility

Observation doors are built in the front setting opposite each row of tuyeres. These doors enable the fireman to watch the fire and keep it in good condition. The operator can work a bar through the doors and down each row of tuyeres should any small clinker formation be noticed on the tuyere blocks. Holes in the fire are easily filled by feeding more coal to the particular retort. As each steam cylinder can be operated independently of the others, the coal supply to each section of the fire is subject to individual control, so that a perfect fuel bed is maintained at all times.

Simplicity—Low Maintenance

Particular attention is called to the great simplicity in design of the Jones "A-C" Stoker. There is an almost entire absence of moving parts. The tuyere blocks are always covered by green fuel and are cooled by the air circulating through them. Each block is held in the retort by a rod operated from the front of the furnace, so that each individual tuyere block may be slipped into place without disturbing any of the others. In fact, every part is readily accessible. Correct design, resulting from twenty-five years' experience. best quality of raw materials and careful manufacture, combine to keep the maintenance cost of this stoker at a minimum.

Adaptability

Since little space is necessary for installation, these stokers are adaptable to unusual local conditions. Ashes are carried away by means of an ash car, steam jet ash conveyor, belt conveyor, hoist or any other suitable ash disposal system. Basements for ashes are not essential. Typical installations are shown.

Service

The engineering department of the Under-Feed Stoker Company, of Canada, Ltd., will be glad to give assistance in the handling of any power plant plans involving the possible use of stoker equipment. As the oldest manufacturers of under-feed stokers their experience enables them to solve unusual combustion problems, whether applied to steam boilers, heating furnaces, drying ovens, or other special work.

A NEW BALANCED VALVE

The following is a description of a new balanced valve, the invention of Mr. Allen Norgrove, Le Pas, Manitoba:

This invention relates to improvements in slide valves for steam engines and has for its object to provide a valve for this purpose so designed that the sliding element of the valve is balanced by the steam pressure in all directions, whereby the tendency of the sliding element to bind against the walls of the valve, due to inequality of pressure on its various sides, is entirely removed.

In carrying out my invention I provide a casing, in which the slide valve is adapted to reciprocate, so constructed

Fig. 2.

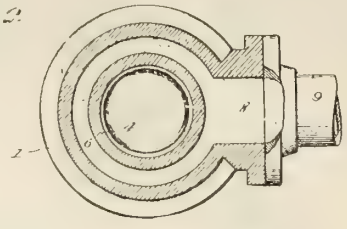


Fig. 1.

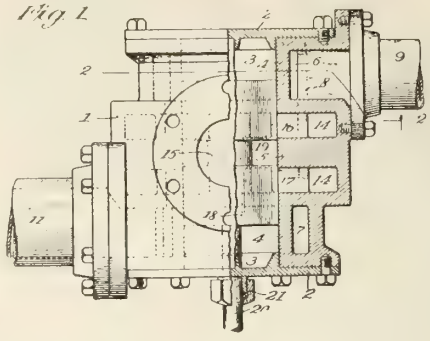

that steam passing into the engine cylinder strikes the slide on diametrically opposite sides, passes around a groove in the slide, and enters a chamber leading to the engine cylinder through diametrically opposite ports disposed at right angles to the first ports through which the steam is admitted to the slide. In a similar manner exhaust steam leaving the engine cylinder strikes against the slide on diametrically opposite sides, travels around the groove in the slide and leaves the groove through two diametrically opposite ports at right angles to where the steam leaving the cylinder first strikes the slide. Two such valves are provided on each cylinder of the engine. It will, of course, be understood that the slide in the valve is reciprocated by suitable mechanism connected with the engine, this mechanism being well known in the art and forming no part of the present invention.

Fig. 4.

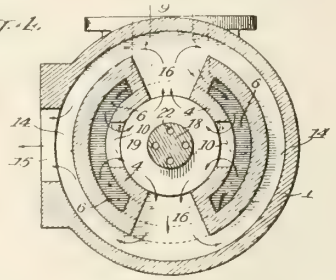

Fig. 3.

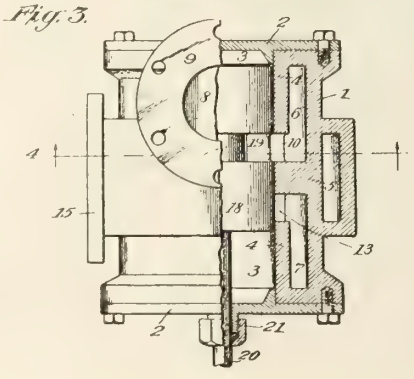

By reference to the accompanying drawing the nature of the invention may be more clearly apparent.

Fig. 1 is a side view partly in section and partly in elevation of the valve in neutral position.

Fig. 2 is a section looking in the direction of the arrows on line 2—2 of Fig. 1.

Fig. 3 is a side view partly in elevation and partly in section, but at right angles to Fig. 1 showing the valve in intake position.

Fig. 4 is a section in the direction of the arrows on line 4—4 of Fig. 3.

Fig. 5 is a full section showing the valve in exhaust position, the section being taken from the same side of the valve as Fig. 1.

Fig. 6 is a section on line 6—6 of Fig. 5.

In the drawings 1 is a valve casing provided at each end with plates 2. The casing is formed with a central valve chamber 3 defined by walls 4, preferably cast integral with the casing. Disposed one above the other and completely separated from each other by a partition 5 are two annular steam chambers 6 and 7. The upper steam chamber 6 communicates by means of passage 8 with the steam feed pipe 9. In the same horizontal plane, but directly opposite each other, are two ports 10 passing through the wall 4, permitting the passage of steam from the inlet steam chamber 6 to the valve chamber 3 (see Figs. 3 and 4.) In similar manner the lower steam jacket 7 connects with the exhaust pipe 11 through passage 12, and communicates with the valve chamber 3 by means of diametrically opposed ports 13 lying in the same horizontal plane and preferably directly beneath the ports 10 in the inlet or live steam jacket. The arrangement of ports for the exhaust steam jacket is in all respects similar to that of the inlet steam jacket.

Surrounding the jackets 6 and 7 is an annular chamber 14 communicating with one end of the engine cylinder through passage 15. Passing through the walls of the jacket 6, in the same horizontal plane as inlet ports 10, are diametrically opposite ports 16 connecting the annular chamber 14 with the valve chamber 3. The ports 16 are so placed that their centre line is disposed at right angles to the centre line of the ports 10 (see Fig. 4). Directly beneath the ports 16 is a similar pair of oppositely positioned ports 17 connecting the chamber 14 with the valve chamber 3, these ports being in the same horizontal plane as exhaust ports 13, but having their centre line at right angles to the centre line of the ports 13, the arrangement being exactly similar to the arrangement shown in Fig. 4 for the steam inlet valve. The outer chamber 15 is not divided horizontally, but webs 5 ft. extending

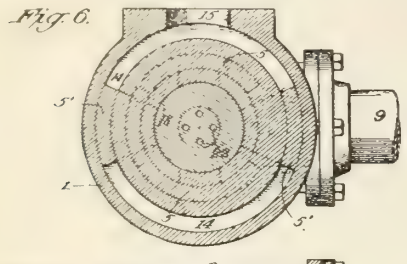
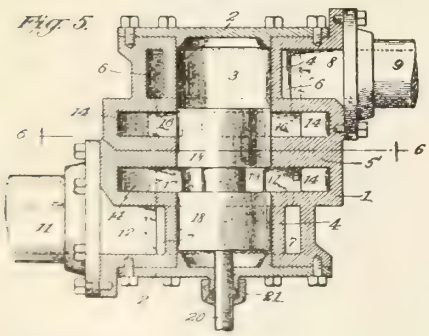
from the partition 5 tend to separate the ports 16 and 17, although these could be well dispensed with at the point where they extend across the chamber 14, only the partition 5 being necessary.

Sliding in the valve chamber 3 is a piston 18 provided on its circumference with an annular groove or duct 19. This duct is preferably made slightly narrower than the partition 5 and is adapted, upon reciprocation, to register with ports 10 and 16 and then with ports 13 and 17. The piston is reciprocated by a rod 20 passing through gland 21 on lower plate 2 and suitably connected with the valve operating mechanism on the engine in any manner well known in the art. The piston is preferably constructed with open ends in order that gases may pass freely from one end of the valve chamber to the other to avoid compression of the gases in the valve chamber. In the drawings I have shown holes 22 passing lengthwise through the piston to prevent compression of the gases in the valve chamber.

In operation the live steam from pipe 9 passes through passage 8 and fills the upper live steam chamber 6. When the piston 18 is moved inward to permit groove 19 to register with ports 10 and 16, as in Figs. 3 and 4, the steam passes





through ports 19, impinging against opposite sides of the piston with equal pressure. The steam then travels around the groove 19 in both directions and out the diametrically opposite ports 16 exerting an equal pressure on the opposite sides of the piston (see Fig. 4). It will thus be seen that the valve is balanced both by the steam impinging against it and the thrust of the steam leaving the groove. From ports 16 the steam passes into the annular chamber 14 and then into the engine cylinder through passage 15. When the engine cylinder is exhausting the valve piston is moved to the position shown in Fig. 5, when the groove 19 registers with ports 13 and 17. The exhausted steam being pushed from the engine cylinder passes through the passage 16 into chamber 14. From chamber 14 it passes out the diametrically opposite ports 17 into groove 19, the pressure being equal upon each side of the piston 18. The steam then passes around the groove 19 in both directions and at the opposite ports 13 into the lower exhaust jacket 7, and thence through passage 12 into the exhaust pipe 11. It will be seen that while the piston is in intake position ports 13 and 17 are closed by the main body of the piston, and while the piston is in exhaust position the ports 10 and 16 are closed by the body of the piston. It will also be seen that when the ports are closed by the piston, the pressure of the steam in the ports against the piston always balances on diametrically opposite sides.

During one cycle of operation in one valve, a similar valve connected with the opposite end of the engine cylinder is operated in a similar manner, but is reversed to feed steam to the engine cylinder while the first is exhausting, and vice versa.

The Large Locomotive Boiler

By F. W. BREWER

THE boiler is essentially the most important part of a locomotive. It must be carefully designed, well made, and constructed of the best material, since, besides the stresses due to steam pressure, it has to withstand the strains caused by expansion and contraction, and also those arising from the severe conditions under which locomotives ordinarily work. Moreover, continues "Locomotive," as it is difficult to determine with absolute accuracy all the stresses to which it is subject, it must be of such strength as to provide an adequate margin or factor of safety. Whatever its defects may be there is no doubt that the ordinary multitubular locomotive boiler, on the whole, is admirably adapted to fulfill the duties peculiar to railway traction. It has one conspicuous advantage in that it enables a large amount of heating surface to be got within a comparatively small compass. This is of the utmost importance, because, other things being equal, the hauling efficiency of the engine is entirely dependent upon the capacity of the boiler, which should be large enough to supply more than sufficient steam for ordinary requirements in order that the engine may be able to respond to special demands upon it for greater power. It being essential, therefore, that steam should be generated as rapidly as may be necessary at all times while the engine is running, the whole heating surface must be arranged so as to effect this object, and this is best accomplished by allowing both steam and water to circulate freely throughout the boiler.

Heating Surface Versus Power

It must not be supposed that a large amount of heating surface necessarily means a high evaporative power, or that a nominally small heating surface invariably implies a low evaporative efficiency. The boiler barrel, for instance, may be so overcrowded with tubes as to render ineffectual the greater proportion of the heating surface presented by them, due solely to the absence of a proper circulation. The disintegration of the steam particles from the water is then consequently retarded, so that the water is apt to rise with the steam and produce what is technically known as priming. Similarly, if the water spaces surrounding the firebox are too narrow, and if the sides of the box are vertical instead of being inclined towards the top, the circulation of the water is again impeded, and the production of steam is consequently injuriously affected. From this it follows that for a boiler of a given diameter and length (including the firebox casing) it is better to employ a relatively moderate number of tubes and to sacrifice some of the width and length of the inner firebox, the alternative advantage being a much better circulation of the water by reason of which a greater quantity of steam is generated in a given time, while the formation of scale is lessened and the tendency to priming reduced. Again, the proportion of firebox surface to tube area, the length and diameter and arrangement of the tubes, apart from their number, and the diameter of the boiler barrel itself are all matters which must be taken into consideration as affecting steam production. Thus the firebox, which is exposed to the incandescent fuel and heated gases, has a much higher evaporative efficiency per square foot than the tubes, so that, within limits, it is always preferable to use as large a firebox as possible, consistent with the work to be done and the quality of the

FAIRBANKS-MORSE

Building a Bigger Canada

THESE are days of progress—days when industry is leaping ahead and Canada is assuming her place in the world of commerce. Giant structures are being reared to house the machinery, men and equipment necessary to a bigger business.

Great highways are being constructed to provide for the easier transportation of Canada's products; elevators, wharves, factories, mills, mines—everywhere the hand of the contractor is set to some big task.

And wherever this construction work is going on, Fairbanks-Morse contractors' equipment is playing an important part—rendering its services as a factor in this work of progress. From the shovel to the steam and electric hoists, from the concrete mixer to the heavy road machinery, drill and jack, to truck and railway car, Fairbanks-Morse equipment is the choice of the contractor, because he knows that behind the smallest tool is the same quality guarantee and service that supports the largest unit of Fairbanks-Morse equipment.

He knows that the Fairbanks-Morse 100% quality seal is the ideal of the Fairbanks-Morse institution—a standard and a guide in building a bigger Canada.

A True Steam Trap-- Not a Hot Water Collector

The object of a steam trap is to save steam.

One glance at some steam traps of the "bucket" or "float" type shows how poorly they fulfill their mission. They are simply receptacles for water that has dropped below the steam point and water instead of conserving steam.

Our first thought, in designing the Steam Trap Sarco, was to build a device that would **save** heat by passing the condensate on to the hot well as **rapidly as it is collected.**

The Sarco does its work with an absolute minimum loss of steam. There is no chance for the condensate to collect and cool. The automatic operation of a sensitive expansion element opens and closes a valve, releasing the hot condensate the **minute it collects. This** conservation of heat units represents a very substantial annual saving, even on steam lines of moderate size.

The Sarco saves money in other ways also. It doesn't waste steam by leakage. It doesn't require constant repairs. It can be installed quickly on any steam line without resorting to expensive construction work. And it costs only one-third as much as a "bucket" type trap.

For all around economy, the Sarco everytime. You don't have to buy it on chance either. Our 30 days' free trial offer gives you the option of putting it to the test at our expense.

fuel employed. The tubes, however, play an important part in the economy of the engine, since they serve to utilize the heat as it leaves the fire box, and by imparting the heat to the main body of water in the barrel, though necessarily less effectively than the directly heated plates of the firebox itself, they provide, nevertheless, an indispensable contribution to the total heating surface.

Length of Tubes

As regards the length of the tubes, practice teaches us that the minimum for modern express engines should be 12 ft. between tube plates, while this length can often be advantageously increased, because in such engines the velocity of the escaping gases is usually very high, and long tubes, therefore, abstract a greater proportion of heat than do short tubes. The tubes are arranged either in vertical or in diagonal rows. Vertical rows are generally considered preferable as it is thought that they promote circulation and assist the rising of the steam bubbles, at the same time allowing solids in the feed water to pass to the bottom of the boiler. To compensate the lower evaporative power of the tubes, their aggregate area in contact with the water is very large compared with that of the firebox, and may be anything from ten to fifteen times greater.

At one period the size of the boiler as a whole was mainly governed by the mean theoretical tractive force which an engine was calculated to develop with a given load at a given speed. That is to say, a boiler of minimum dimensions was generally provided, and this sufficed for moderate needs. Modern requirements, however, have by degrees reversed this order of things until to-day it may more correctly be said that the hauling power is only limited to the extent to which the size of the boiler can be increased. It is now fully recognized that the actual—as distinct from the nominal—tractive force is appreciably augmented by enlarging the steaming capacity for a given cylinder volume. The dimensions, therefore, can only be said to define the minimum size of boiler necessary for a given theoretical tractive power. They cannot of themselves be taken as a general indication of the absolute power, for that is inseparable from the boiler capacity, and will be greater proportionately to the increased facilities for steam production. Most British locomotives, it is true, have done exceptionally good work, having regard to their nominal tractive force and heating surface, and while there are many other conditions which have their influence on the hauling efficiency (such as the setting of the valves, the diameter of the blast-pipe, the weight on the driving wheels, and so on), the fact remains that it is now generally advisable to use a much larger boiler than that determined by the former methods of calculation. The most that can be said is that cylinder volume is an approximate guide, while the maximum size of boiler possible is determined by considerations which lie quite outside. These are the restrictions due to height, width, length, and weight. Generally speaking, the height of the chimney-top above rail-level must not exceed 13 ft. 6 in.; the width, or space available transversely between the tires of the driving wheels, so that it will be seen that these two limitations are the primary ones, and being interdependent are alone sufficient to fix the size of the boiler diametrically. Owing to difference in the vertical loading gauge, what might be possible on one line might be out of question on another, but it may be taken as a general rule that large-diameter boilers and large driving wheels cannot go together. The diameter of the one or the other must be kept down, and since the boiler capacity is of paramount importance, it may be preferable to use relatively small driving wheels, more especially as the tractive power for a given cylinder diameter and piston stroke will then be correspondingly greater.

As regards the length of the barrel and firebox combined, this must be such as to permit of the rigid wheelbase being short enough to enable the engine to traverse safely the shortest curve on the line over which it will be required to run. There is also an assumed limit to the length to which tubes can be usefully extended. The same may be said respecting the length of the firebox, as, although the objection to the use of long coupling rods is removed by placing all the driving wheels in front of the box and employing a supplementary carrying axle underneath it, yet very long grates are difficult to fire efficiently. The condition as to weight depends upon the strength of the permanent way and bridges, but on all the more important main-line railways a reasonable allowance is now made for the probable development of the locomotive in this respect.

But it will be understood, no doubt, that there are certain other factors which have to be reckoned with in connection with the increase in boiler capacity. For example, in the case of express engines the limit to which a boiler can be advantageously enlarged for a given cylinder diameter is reached when the cylinders, owing to back pressure and the necessarily reduced port opening high speeds, can use only a comparatively small quantity of the steam generated. This limit will be determined by the particular type and arrangement of the valves and valve gear, by the respective areas of the steam and exhaust passages, and by the diameter of the blast-pipe, which details ought to be planned with a view to increasing the positive pressure on the pistons, without, however, reducing the compression below the amount necessary to absorb the momentum of the moving parts at the end of each stroke. It is not easy to adjust these matters to a nicety, but the big boiler, if provided with adequate grate area, is of itself a help in this connection, since it allows of a larger blast nozzle being used; and the latter, by diminishing back pressure, permits the cut-off to be later, and this, in turn, enables the engine to haul a heavier load at a given speed, or to take a given load at a higher speed, as may be required.

Insure Constant Level

The most economic way to operate boilers is with constant water level and uniform constant inflow. With the level held constant at middle gauge the greatest amount of heating surface is presented to the hot gases and the maximum amount of steam space is available.

Vigilant Feed Water Regulators

meet these conditions in a very satisfactory way. They are easily adjusted to maintain an absolutely constant water level at any arbitrarily determined height in boilers and they feed continuously with perfect uniformity.

Clearance Sale of High Grade Technical Books

FOR several years we have maintained a Technical Book Department, handling high-class books published by various well known publishers. For various reasons we have now decided to discontinue our Book Dept. and in order to clear out what stock we have on hand we offer the following books at prices considerably lower than the regular selling price. Each item represents high quality at bargain prices. These books will not last long—first come first served. This is a fine opportunity to add to your technical library.

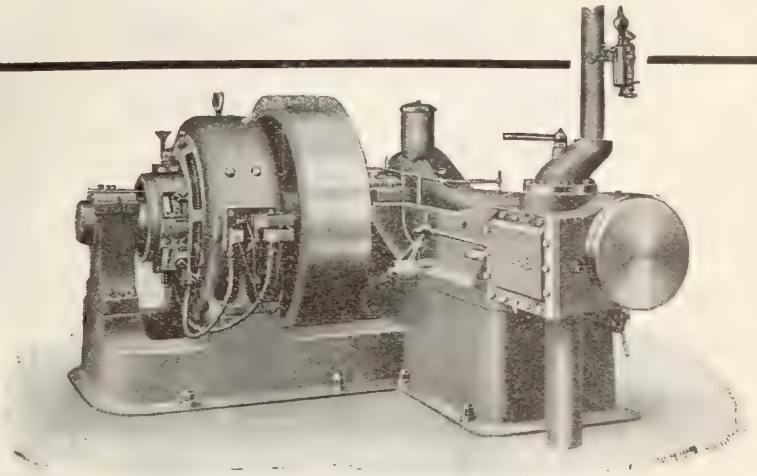
ROBB POWER PLANTS

For Quality Equipment

We specialize in the design and construction of power plant equipment. Our engineers are prepared to investigate your problems and advise on the most economical machinery for your needs.

We can supply Corliss, Slide-Valve, Vertical, Horizontal, Simple and Compound Engines, and Water tube, Return tubular, Improved Scotch Marine, and Portable Boilers.



Robb Equipment is known to engineers and power plant superintendents for its long and dependable service, standard quality and modern design. When you are in the market—remember it will pay you to purchase equipment that has won the confidence of leading engineers.

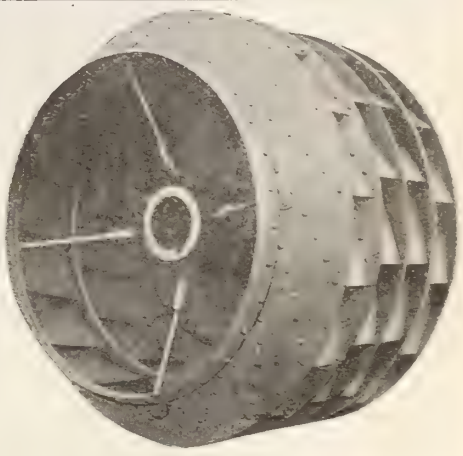
GREEN'S

HI-EFFICIENCY HI-SPEED

RADIAL FLOW FANS



Economical, Sturdy, Efficient

Green's Radial Flow Fans are possessed of many advantages. They require approximately 20% less horse power than any other fans. Are so designed that the rotor and bearings are easily accessible without changing the alignment or dismantling the flue work. Any blow back through the fan inlet or dead space on the fan wheel is impossible due to the design of rotor and housing. They run at speeds best suited for direct connection to turbines or motors and are also suitable for gear or belt drive.

Consult our engineers. They will gladly furnish you complete information with regard to fans to cover your individual requirements.

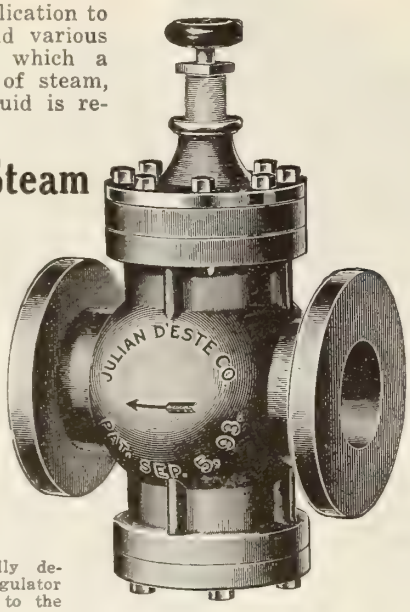
HINTS TO BUYERS

CURTIS Engineering Specialties

Universality!

For universal application to all the varied and various conditions under which a reduced pressure of steam, water or other fluid is required the

Improved Steam Pressure Regulator



has no equal.
It is compact and self-contained, without levers, weights or projections.
No glands or packing; no drip for leak of steam or water. Suitable for any boiler pressure; made entirely of metal: is a lock valve, very simple and sensitive.
Send for leaflet fully descriptive of this Regulator (contains price list) to the manufacturers.

Canadian funds are accepted at par at Montreal.

DEPARTMENT OF LABOUR
Ontario Government

Minister: Hon W. R. Rollo **Deputy Minister: W. A. Riddell, Ph.D.**

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a **Stationary** steam plant of 50 B.H.P. or over, and everyone operating a **Hoisting** steam plant working at a pressure of 20 pounds or over, irrespective of horsepower and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a certificate from the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

All applications should be mailed to the Chairman of the Board. W. C. McGhie, Department of Labour, 15 Queen's Park, Toronto.

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering, the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., ch. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, 15 Queen's Park, Toronto. D. M. Medcalf, Chief Inspector of Steam Boilers.

MONCRIEFF'S

"UNIFIC" GAUGE GLASSES

The British Navy uses "Moncrieff's" "Unific". It is the kind that lasts.
It is a special feature of the "Unific" that it does not readily corrode; resists extreme changes of temperature and withstands the highest working steam pressure. In consequence it has a long life, justifies a higher price than the soda lime glasses, and is, indeed, the more economical purchase in the end.

Write for our catalogue.

The Safe and Certain Boiler Cleanser

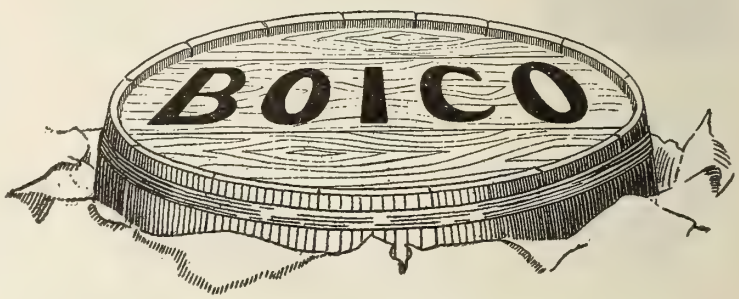
PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**

BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.



Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

CHAPTER I

COMBUSTION ENGINEERING

How the new chief met the problems of fuel economy and plant efficiency

Jim Payne had been chief engineer of the Great Western Hotel for nearly twelve years. Just now, however, he was sorely peeved; he had asked for an increase in salary and had been turned down. As a consequence he had tendered his resignation. The manager had refused to give the desired raise because he was not quite satisfied with the manner in which the operating costs were piling up. Of course, fuel, oil, materials, supplies and other expenses had gone up nearly every day, but the manager was not satisfied with the statement that some improvement could not be made.

When Payne tendered his resignation the manager asked him to recommend a man for the place. He recommended the young assistant chief, who had been in charge of the detail work and most of the repairs for nearly three years.

"It's up to you now to make good," Payne told the assistant when he informed him of the latest move. "I guess I have let my years get away from me without taking advantage of the opportunities there are for the man who knows Combustion."

That morning the general manager of the hotel called the assistant into his private office for a short talk. "These are serious times," he said, "and every power plant owner, like myself, must look forward to greater saving in fuel. There is a real opportunity here for the man who knows or the man who will study Combustion."

The new chief readily saw that the new job called for more brain work than physical work and "*it was evident that employers were willing to pay more for a strong mind than for a strong back.*"

Presently the new chief wandered back to his desk and extracted a large report or dope sheet. On this he began to write a thousand and one questions about the plant, directed at himself. He was cross-examining himself, much as a shrewd lawyer would examine a witness on the stand.

The questions ran something as follows:

WHAT are your chances for real success?

Do you realize the opportunities that a knowledge of Combustion offers to the man who wants to be more than merely the average?

It is not so much a strong back today as it is a strong mind that counts!

The man who knows Combustion can state his own salary and his services are always in demand.

Would you like to have the opportunity of getting a thorough knowledge of Combustion and Boiler Room Management in your spare time and at a very small cost, payable monthly if so desired? Jos. W. Hays, author of the Course and Educational Director, formerly Consulting Combustion Engineer of the U. S. Navy; W. L. Abbott, Chief Operating Engineer of the Commonwealth Edison Company; Fred R. Low, Editor of "Power"; Prof. S. W. Parr, Department of Chemistry, University of Illinois; Joseph Harrington, formerly Administrative Engineer, U. S. Fuel Administration; David Moffat Myers, formerly Advisory Engineer for the U. S. Fuel Administration; Arthur L. Rice, Editor of "Power Plant Engineering," and I. E. Moultrop, Bureau of Construction, Edison Electric Illuminating Co., have now made it possible for you, thru the Hays Course in Combustion Engineering and Boiler Room Management, to obtain a thoro knowledge of Combustion in your spare time without interfering with your present work in the least.

This Free Book

will tell you some interesting pointers that the average power plant and boiler room man should know, particularly about Combustion Engineering

The coupon will bring to you, without any expense whatever, a copy of this interesting book, covering power plant and boiler room management. It tells you how other men like yourself have, thru the Hays Course, achieved real success and how the same can be made possible in your case.

If you are determined to get out of the ordinary class and to push ahead where your services will be worth much more than they are today, get your copy of this book at once. It will help you from the time you receive it. It will interest and inspire you because it shows a better way toward bigger things. It also shows how, thru the Course, in addition to obtaining a knowledge of Combustion, you get, as well, a liberal education, paving the way for real executive ability.

Your request for this book will obligate you in no way whatever—merely clip the coupon below and return it today with your name plainly written or typed. Promptly upon receipt of the coupon the book will be sent you—absolutely FREE.

The Design of Moore Steam Turbines Prevents Steam Leaks

Ample surfaces at the joints have been provided to prevent leakage of steam—also the number of vertical joints have been reduced to a minimum. In a turbine having numerous vertical joints it is almost impossible to prevent leakage and consequent loss of efficiency in operation.

The careful designing to prevent all steam leakage is but one feature of Moore Steam Turbines. Send for our booklet. It explains fully the others.

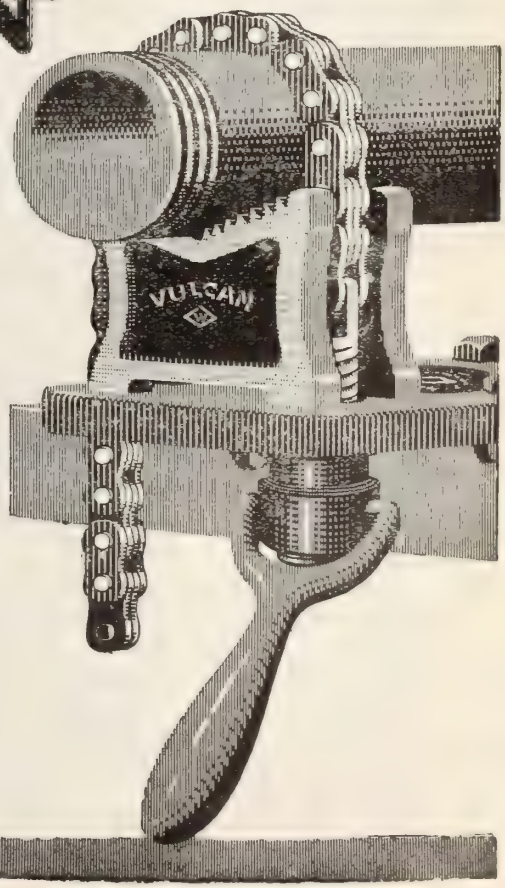
WILLIAMS' "VULCAN" DROP-FORGED CHAIN PIPE VISE



IN general, you know there's no comparison between a cast and a wrought tool.

The same principle applies to pipe vises.

Williams' "Vulcan" No. 4, for 3/8 to 8 in. pipe, is stronger, quicker in action and cheaper.

3 sizes for 1/8 to 8 in. pipe—at your dealer's.

LADD

WATER TUBE BOILER

The Ladd Water Tube Boiler is a combination of rugged, simple and accessible construction.

Built in any size and for any of the many methods of firing—stoker, oil, gas, powdered coal, etc.

Our Engineering Department will be glad to co-operate with you on your boiler problems—no matter how intricate or elaborate they may be.

Our catalogue will be of interest to you.

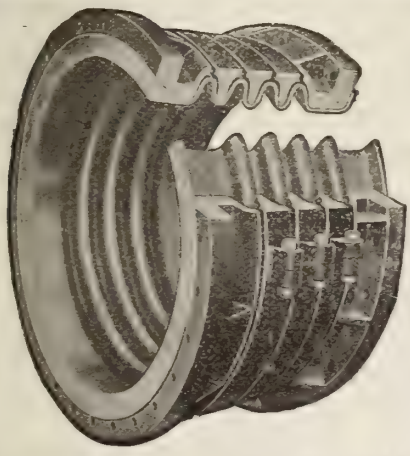
Chicago Office: 528 McCormick Bldg.



BADGER

SELF-EQUALIZING EXPANSION JOINTS

Our Expansion Joints can be installed in a pipe line as easily as any flanged fitting; they have no complicated parts; they are compact; the greatest diameter is usually that of the flanges; hydraulic test on every joint before shipment; they will safely care for expansion on high and low pressure and exhaust-pipe lines.

Gates Refractories, Limited

Contractors for all Kinds of Power Plant Brickwork

If it's Fire Bricks, Fire Cement or any kind of refractory materials see Gates. Prompt attention assured.

Our engineers are experts in all kinds of refractory work. Their wide and varied experience enables them to cope with the toughest problems and advise on the proper materials for maximum efficiency. Consult them on any problems—without obligation.
Remember our specialties are Boiler Setting, Furnace Building, and Oven Work. Write us for estimates.

Write us for full particulars of the Gates' special door arches, furnaces and refractory linings.

Upper illustration: Showing how V-Buckets not only elevate material, but act as scrapers on the horizontal.

Jeffrey V-Bucket Conveyer used to carry ashes from under boilers.

Coal being distributed to bunker in boiler house by a Jeffrey V-Bucket Conveyer. Coal passes direct to elevator or first through a Jeffrey Single Roll Crusher and then to Elevator.

The Jeffrey V-Bucket Elevator-Conveyer

Is economically adapted to the small Power Plant

The Jeffrey V-Bucket Conveyer may be used either as a run-around Conveyer or as a Combined Elevator and Scraper, and where conditions will not permit of a vertical elevator being extended sufficiently high to spout the material to points desired.

The V-Bucket Conveyer is also of advantage in places calling for a run-around conveyer where the capacity is less than 50 tons per hour, as given by our small pivoted bucket carriers. It is also especially adapted to the handling of slack and stoker sized coal.

Jeffrey Coal and Ashes Handling Machinery includes Bucket Elevators, Conveyers of the Scraper, Belt, Apron, Pan and Drag Chain Types, Single Roll Crushers, etc.

Consult Jeffrey Engineers about your problems.

NORWALK
AIR & GAS · COMPRESSORS

The Right Capacity

Guesswork is costly, and particularly so in compression service. Under-equip and you cripple a plant; overstep your needs and you invite waste, besides making a larger initial investment than is necessary.

Economy lies in the right capacity for full and sure results under all conditions, and Norwalk engineers protect you by determining that capacity **before** the installation is made.

You are invited to call upon us for counsel in connection with any compression problem. We will give you the benefit of forty years' experience.

Farnsworth Equipment Reduces Coal Expenses to a Minimum

Big plants, all over the world, are reducing their coal bills. Some 20% or more! Farnsworth Closed Condensation Systems are not an experiment. Their use has **proven** more economical in the long run. Experience shows that in the majority of cases the equipment pays for itself in from three to six months.

New Canadian Factory

The Canadian Farnsworth Company, engineers and manufacturers of condensation pumps, automatic boiler feeders, return steam traps, all of the duplex type, and general steam utilities, have opened and are now operating their new factory at 1—24 Hillingdon Ave., Toronto. These lines were formerly manufactured by the Canadian Fairbanks-Morse Company.

Send for copies of bulletin on Steam and Condensation; they are interesting and instructive.

MORRISON

STEAM GOODS

"Beaver" Globe Valve
Bronze

The Morrison Standard Is High!

Morrison's Steam Specialties are made by skilled workmen of materials which long experience and modern science show to be best.

Though every care is taken with their construction, this is not enough. To conform with the Morrison Standard every specialty must be factory tested to withstand stress far in excess of that which it will be called upon to endure in actual service.

This high safety factor is why users recommend Morrison products every time—they always make good.

BELLISS & MORCOM, LTD.

Engines and Air Compressors

The fact that some of Canada's largest engine rooms are equipped with Belliss and Morcom Engines and Air Compressors proves conclusively that they are among the most reliable and economical engines on the market, because such firms are invariably keen buyers. Illustration shows a Belliss and Morcom installation in the Power Plant of the Montreal Tramway Co. When you are in the Market do not fail to investigate the Belliss and Morcom line. **Full information on request.**

BOILERS

FOR POWER AND HEATING PURPOSES

You will find Waterous Horizontal Return Tubular Boilers in the largest industrial and municipal power plants in the country. There are reasons for this. They are economical of fuel, carry a big reserve steam pressure for use in emergencies, can be used with hard and dirty water, and are readily cleaned and easily taken care of. They cost little new; their upkeep and maintenance expense is negligible.

Waterous Horizontal Return Tubular Boilers are built in all sizes from 40 inches by 10 feet to 72 inches by 18 feet. Most standard sizes are carried in stock. If we cannot supply at once from our yards we can turn out your order for you in quick time. On the next boiler you need let us quote you prices and delivery.

Boilers in Stock

1—54 x 14 Horizontal
2—60 x 14 "
4—66 x 16 "
14—72 x 18 "
2—40 H.P. Locomotive

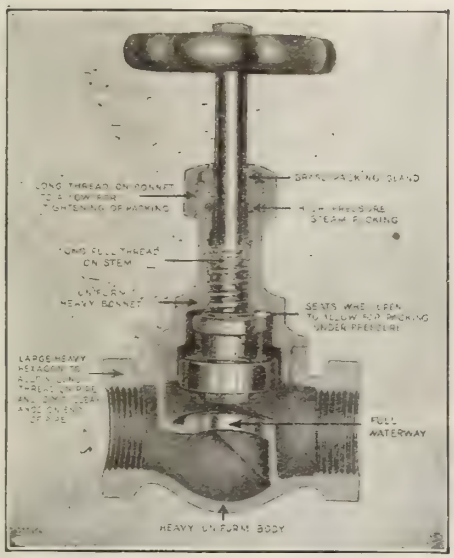
The "EMCO" Composition Disc Valve



LONG THREAD ON BONNET
TO ENSURE TIGHTENING OF PACKING
BRASS PACKING GLAND
LONG FULL THREAD ON STEM
UNIFORM HEAVY BONNET
SEATS WHICH TEND TO YIELD AND INCREASE UNDER PRESSURE
LARGE HEAVY HEXAGON TO ASSIST IN SECURING TIGHT JOINT
FULL WATERWAY
HEAVY UNIFORM BODY

A-840

This design is approved and registered by inspectors of steam boilers for a pressure of 175 pounds, in the following provinces:—

Globe Valve A-840

British Columbia -	No. 2590
Alberta - - -	No. 1102
Saskatchewan - -	No. 2365
Ontario - - -	No. 1755

This "Emco" Composition Disc Valve with its nine pronounced features of superior construction has firmly established itself with engineers, because of the service it renders under constant working pressure.

The accompanying illustration enumerates its outstanding "good points," and coupled with these are reserve strength and durability.

"Emco" A-840 is made of the best bronze metal and each valve is hydraulic tested before leaving our factory.

When buying specify our lines. They are carried in stock by the larger and more progressive jobbers in Canada.

New Truths and Old Fallacies

Fusibility of Alloys—*Continued*

Among babbitt mixtures "Copper Hardened" babbitt has been and is yet extensively used. There is something catchy in the word that appeals to the imagination as expressing a degree of hardness that would give relief from the most prolific cause of bearing troubles from squashing. It also has a tinny appearance and conforms to the usual physical tests for toughness and malleability and the price is much lower than Genuine, and every prospect pleasing.

This is a Quaternary formula, containing four ingredients, and its tin content usually ranges from 40 per cent. to 44 per cent., which approximates the quantity of tin used in Wiping Solder.

Now a solder must have a low fusibility and flow readily, so that it will follow quickly the soldering iron or copper as heat is applied. Wiping Solder not only has a low melting point, but possesses a peculiar characteristic of remaining in a pasty state throughout a range of temperature of 60° Fahrenheit before it solidifies, which accounts for the fact that it can be applied to a joint with a wiping cloth; hence its name, Wiping Solder.

"Copper Hardened" babbitt contains not exceeding two per cent. of copper, because it is not considered good practice to use copper to an extent exceeding 5 per cent. of the tin content of an alloy. However, this percentage of copper does not apply in every case, as in lead base metals, with low tin content or no tin, there should be no copper. Neither does a "Copper Hardened" babbitt possess any special antifrictional qualities nor the vaunted hardness, and when frictional heat causes it to fail, because of its low fusibility, the underlying reason is not suspected.

Get Away From Check Valve Troubles

by installing

The Penberthy Double Plug Check Valve

on Your Steam Lines

GOVERNMENT APPROVED FOR 200 LBS. PRESSURE

The illustration above shows a sectional of this high-grade check valve. Note the liberal thickness of metal evenly distributed throughout. Makes the valve strong and durable. Will give long and efficient service.

The double plug construction makes it possible to take the valve apart if mounted on a wall pipe without disconnecting same from the pipe. The plugs also act as bearings for the disc carrier pin and in case of wear it is only necessary to renew either plugs or pin, making valve as good as new. The top plug "A" is also removable for insertion of screw-driver when regrinding disc and seat is necessary.

Stocked by leading jobbers everywhere.

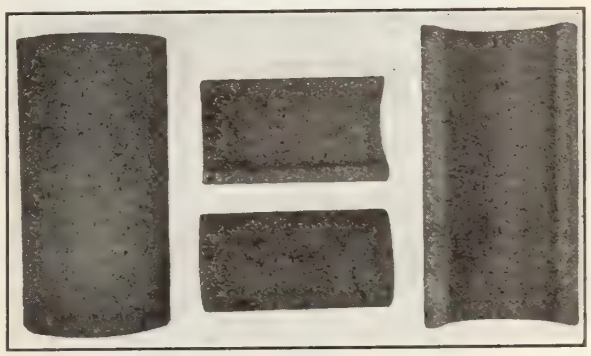
Does a Service Record of Twenty-Two Years Mean Anything to You?



Specimens of Nonpareil Cork Covering after serving for twenty-two years on a brine line in the plant of the Hawley & Hoop Confectionery Company, New York City.

What kind of "verdict" would you pass on a covering that withstood brine line service for twenty-two years and was still in good condition when removed from the pipes? Would not such a record impress you as being an indication of unusual merit?

The photograph above shows four half-sections of Nonpareil Cork Covering, installed on brine lines in the plant of the Hawley & Hoop Confectionery Company, New York City, in 1897. Twenty-two years later—in 1919, to be exact—when this covering was removed, it was in excellent condition and equal to the task of saving refrigeration for several years to come.

Now the Nonpareil Cork Covering of to-day affords a distinct advantage over that which was made in 1897. In those days, Nonpareil Cork was protected from moisture by wrapping it with canvas and applying several coats of lead-and-oil paint—a job that could be performed only after the covering had been erected. But the improved Nonpareil Cork Covering—the covering you get to-day—is thoroughly waterproofed at the factory. It is coated inside and out with waterproof mineral rubber—a material that repels moisture indefinitely.

"Nonpareil" is the short way of saying, "A covering for brine and ammonia lines that insures better service for a greater number of years."

Send for the 64-page, illustrated book, "Nonpareil Cork Covering for Cold Pipes." The facts contained in it are specific, interesting and valuable—and there is no charge for it whatever.

The De Laval Oil Purifier

took this dirt out of used lubricating oil AFTER it had passed through a 'Filtering' system.

Some very convincing demonstrations of the superiority of the De Laval Method of Oil Purification over other methods have been reported by many large manufacturing concerns where the De Laval Method took out a large quantity of carbon, metallic particles, grit, dirt and water from used lubricating oil—**after** it had been passed through extensive settling and filtering systems.

The De Laval Method is simple, continuous and economical—removes all solid impurities and water, and restores the oil to its original usefulness.

The Oil Purifier is used for reclaiming and purifying lubricating oil, cutting oil from chips, cutting oil from soda-wash, hardening room drawing and quenching oils, fuel oils, etc.

Write to nearest De Laval office on your business stationery for Oil Purification Bulletin No. 100 and reports on the De Laval Method.

A complete experimental department is maintained for working out the problems of our customers by means of centrifugal processes.

A Series of Articles on Power Plant Management

This Article Deals With the Combustion of Fuel Oil, and Its Comparative Merits With Those of Coal—The Selection of Burners and Features of Operation Are Dealt With

By ROBERT JUNE

THE shortage of coal and the high prices obtaining have led to the adoption of oil as a fuel for many boiler furnaces, and to the serious consideration of the desirability of its use in many other plants. In dealing with the combustion of fuel oil, it may be well at the outset to discuss the question—when is it advisable to substitute oil for coal under boilers?

Oil Versus Coal

Kent, in his pocket book, gives the following table, based on oil of 19,999 B.t.u., weighing 7.757 pounds per gallon, with 42 gallons, or 315 pounds per barrel:

Coal B.t.u. perlb.	1 lb. oil = .. lbs coal	1 bbl. oil = .. lbs. coal	1 ton coal = ..bbls. oil
10,000	1.9	598	3.34
11,000	1.73	544	3.68
12,000	1.58	499	4.01
13,000	1.46	460	4.34
14,000	1.36	427	4.68
15,000	1.27	399	5.01

It is approximately true, therefore, that one lb. of oil is equivalent to 1½ lbs. of coal, and that four barrels of oil are equivalent to one short ton of coal. On the above basis, therefore, oil at $2.00 per barrel, is equivalent to coal at $8.00 per ton.

There are other factors than a straight comparison of initial costs, to be taken into consideration, however, such as availability of both fuels, increased boiler efficiency, and comparative costs of labor and storage.

Advantages and Disadvantages of Fuel Oil

The advantages of liquid fuel may be summarized as follows

1. Reduction in number of firemen, coal passers, helpers, etc., by about four-fifths.

2. Fires readily lighted, easily regulated to suit plant demand, and can be promptly extinguished in case of emergency, as with water dropping out of sight in gauge glass. Boiler can be brought to 150 lbs. steam pressure with cold water in half an hour.

3. Higher efficiencies and capacities. Combustion is nearly perfect, as excess air is reduced to a minimum; furnace temperature may be kept practically constant, as furnace doors need not be opened for cleaning or working of fires.

4. Oil storage occupies less space than coal storage. Furthermore, this storage may be at a greater distance from the boiler.

5. Oil in storage does not decrease in heating value as does coal, nor is there the same danger of spontaneous combustion.

6. There is little refuse with oil, and this is easily disposed of.

Oil firing assures cleanliness and freedom from dust and ashes in boiler room, with constant saving in the wear and tear on equipment. It minimizes annoyance and damage to surrounding property.

7. There is no loss by banking.

8. Smoke can be practically eliminated.

9. Lower temperatures in boiler room prevail.

10. As there is less excess air, the area of the stack need only be three-fifths to two-thirds that required for coal. Hence, if a plant has insufficient draft with coal, a change to oil may make additional stack capacity unnecessary.

11. There is better diffusion of heat in an oil burning furnace. Hence, less burning out of boiler tubes. As firing tools are not required, there is no damage to furnace linings from this source.

The disadvantages of fuel oil are:

1. Oil must have flash point of 140 deg. F., or more, in order to minimize the danger of explosions. On account of fire risks, use of oil is prohibited by some city ordinances.

2. City ordinances may impose burdensome conditions relative to location and isolation of storage tanks, as for instance, that they be located underground and at least 30 feet from the nearest building.

3. Boiler upkeep and furnace maintenance will be higher with oil than with coal unless boilers and furnaces are especially constructed for use with liquid fuel. When feed water contains scale-forming constituents in any large quantity, cost of repairs is apt to be considerably increased owing to the intense temperature developed at the furnace.

4. On account of offensive odors, combustion of oil is prohibited by some cities. The burners also make a roaring noise objectionable in some districts.

5. There is danger of waste due to improper operation of burner and also the tendency of oil to creep by valves, and leak.

Comparative Efficiency—Oil and Coal

Coal burning boilers operating at 80 per cent. efficiency have at times been reported, but the cases are so exceptional as to exclude them from consideration in a practical discussion. Seventy per cent. to 77 per cent. efficiency undoubtedly represents the best station practice for coal burning boilers, and it is reasonably certain that nine coal burning boilers out of 10 operate at efficiencies less than 70 per cent.

With fuel oil, efficiencies as high as 82 and 83 per cent. have at times been obtained, and it is not at all unusual to obtain efficiencies of 78 per cent. With reasonable care and attention, any oil burning furnace should be operated day after day at 75 per cent. efficiency. Generally speaking, therefore, there is a clear gain of 5 to 10 per cent. in boiler efficiency through the use of fuel oil.

Conditions Surrounding Combustion of Fuel Oil.

The following conditions must be complied with in the successful combustion of fuel oil:

1. The oil must be thoroughly atomized. This is to be secured by proper selection of burner.

2. After atomization has taken place, the oil must be brought into intimate mixture with exactly the right quantity of air for its complete combustion. This condition is met by introducing air through the checker work under the burners and by controlling the quantity so introduced so that it varies with the amount of oil which is being fed.

3. Combustion must take place in the presence of refractory materials which will radiate the heat. Particular care must be taken to design a furnace which

will stand up under the high temperatures developed.

4. Combustion must be complete before gases reach heating surfaces of boiler. Otherwise the process of combustion will be stopped, possibly to be removed after the oil and air reaches the stack. This requirement is met by providing very large combustion spaces with a gas travel of sufficient length.

5. Overheating and blistering of boiler will result if the heat is localized on any portions. This condition is to be avoided by proper selection of burners and by their suitable location.

Selection of Burner Types.

In this country the burners in use are two general types steam and mechanical atomizers. In Europe, a third type, known as the vapor or carburetor, is used.

As between the steam atomizer and the mechanical atomizer, engineers of stationary boiler plants have been almost unanimous in their choice of steam atomizers; whereas marine engineers have come to depend chiefly on mechanical atomizers. A good example of the mechanical spray burner is the Korting.

The steam atomizers are divided into two groups, of which the Peabody and Warren are typical outside mixers; the Hammel, Kirkwood, Branch, and Williams, of the inside mixers. As far as results go, there is not a great deal to choose between mechanical and steam atomizers. Mechanical is preferable where feed water is difficult or expensive to obtain. The steam atomizer possesses the advantage of being more flexible, having greater range of capacity and of costing less to install, notwithstanding that it requires two lines of pipe—oil and steam—whereas the mechanical requires only the oil line.

The steam atomizer, moreover, is more readily installed or taken out of a coal burning furnace. It possesses the further advantage of requiring a lower oil pressure than mechanical burners. The steam required for atomization is from two to four per cent. of the output of the boilers.

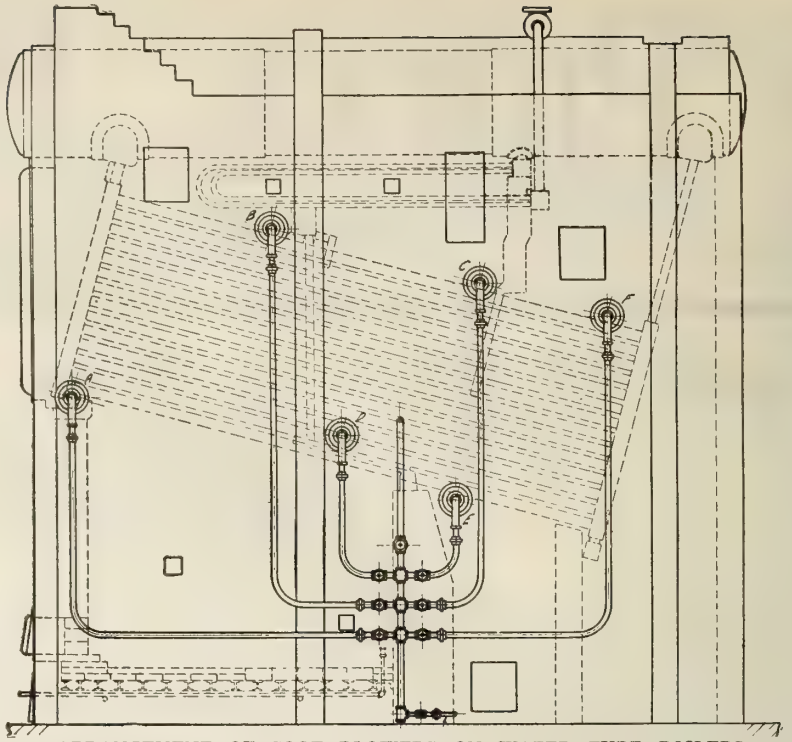
Notes on Operation.

Oil Pressure: With steam atomizers, oil pressures ranging from 25 to 50 lbs. are adequate. The mechanical burner, on the other hand, requires pressures ranging from 50 to 250 lbs.-200 lbs. being a favorite pressure. With all oil burners, a steady pressure is essential. With mechanical burners, it is so necessary that large air chambers are required on the oil line if pressure is obtained by means of duplex reciprocating pumps.

To overcome the use of air chambers, rotary and screw pumps are being used in the navy, these pumps giving a steady pressure of oil with little or no air cushioning.

Heating of Oil

The reason for heating oil is to increase its viscosity, and not for any thermal advantage. Steam atomizers will handle oil of greater viscosity than the mechanical atomizer. Hence, exhaust steam passed through coils will answer for this purpose. By this means the oil may be heated to 100 or 125 deg. F., temperatures which are usually satisfactory.



ARRANGEMENT OF SOOT BLOWERS ON WATER TUBE BOILERS.

With the mechanical burner, however, it is necessary that the viscosity of oil be reduced very considerably. Hence, the oil must be heated to a temperature of 120 to 280 deg. F. This requires a special oil heater.

Air Regulation

With oil, a very bright and intense white fire usually indicates that an excess of air is being used. It is best not to attempt to judge the fire by its color, but to regulate the air until a light brown haze appears at the top of the stack. It should be remembered that a clear stack gives no indication of excess air. It should further be remembered that the light brown haze at the top of the stack just referred to, can be produced by one or two burners, while all the other burners are using an excess amount of air. Probably the most satisfactory method to employ is that of automatic regulation of the air supply for the individual boiler. There are one or two very excellent systems now on the market for this purpose.

Lighting Fires.

In lighting fires, the first operation is to place a lighted torch directly under the burner pit, then turn on oil. The spray must never be started before lighting the torch. If this is done, the oil will be injected into a dark furnace and an explosive mixture may be formed which may cause serious damage if ignited.

Oil Feeding Systems.

In the usual feeding system, steam driven pumps installed in duplicate, draw the fuel from the supply tank and deliver it under pressure to the burner. The piping is by-passed so that either pump can be shut down and repairs made without interfering with the operation of boiler.

It is usual to use the exhaust steam from the pumps for the purpose of heating the oil before it is supplied to the burners. Care should be taken, however, that the temperature of the oil is not raised above the flash point or carbon deposits are very apt to form in the supply line. The suction line between the storage tank and oil pressure pump should be provided with a strainer to prevent clogging of burner with foreign matter. In order to prevent excessive pressures, a relief valve, set at a definite maximum oil pressure, should be placed between the pumps and the burners.

If desired, an oil meter can be installed for the purpose of taking the consumption of each individual boiler. As a matter of precaution, all oil piping should be installed in such manner that it can be drained back to the storage tank in case of necessity. In order to insure continuous operation under all conditions, strainers, heaters, meters, piping, etc., are installed in duplicate in many plants. The supply of steam is regulated by the pressure in a separate main, common to all burners, the pressure in the main bearing a certain, predetermined relation to the oil in the main. In most installations, the supply of steam and oil at the burner is regulated by hand, to meet the requirements of the individual burner.

Low pressure systems are ordinarily operated under standpipe pressures. The oil is drawn from the storage tank, usually located underground, by the steam pump, which runs continuously,

and always keeps the standpipe well supplied with oil. The oil flows from the standpipe under whatever head may be desired. When the boiler is not in operation the standpipe is drained back to the storage tank. This system is very simple and is an inexpensive installation.

Next month we will discuss furnaces for burning fuel oil, soot deposits with oil, and specifications for the purchase.

Furnaces for Burning Fuel Oil

The design of the oil burning furnace is more important than the type of burner. Incandescent brick work around the flame is desirable, but where this is impossible, the next best arrangement is that of using a flat, broad flame, burning close to a white hot checkerwork floor through which the air is continuously admitted. The path of flame in t furnace must be such as to insure a uniform distribution of heat over heating surfaces of the boiler without any direct flame impingement.

Under no circumstances should the flame extend into the tube. The best arrangement is one where the furnace is located under the first pass of the boiler. With this arrangement the heating surfaces of the boiler readily absorb radiant energy from the incandescent fire brick. Arches, target walls, and similar constructions are not satisfactory and may prove quite dangerous on account of localization of heat. This localization may cause the burning out of tubes, or bagging of shell, to say nothing of limiting the capacity of the boiler.

Soot Deposits in Oil Fired Boilers

The soot deposit resulting from the combustion of oil is in the nature of a pure carbon mixed with a slight amount of oil. It is somewhat fluffy in appearance and adheres to the tubes, but is easily cleaned and removed from the boiler under the operation of a steam jet. It is entirely different in character from the soot resulting from the combustion of coal on account of the absence of ash, etc., and the presence of greater or less quantities of unburned oil. which, going through the boiler, tend to deposit on the tubes in combination with the soot. If this formation is not removed at regular frequent intervals, it soon crystallizes or carbonizes on the tube and must be scraped off with rods or bars.

Soot deposits from oil fired furnaces have a much greater insulating effect than those occurring with coal fired furnaces. There are two reasons for this; first of all, the deposit is in the nature of a pure carbon which has greater insulating properties than various ash constituents found in soot from coal; second, the deposit being of a somewhat fluffy adhesive nature, is usually found to envelope the entire tube as compared with coal deposit, which usually consists of soot, dust and ashes building on top of the tube and leaving the underside more or less clean.

For some time after oil came into use for boiler furnaces, the impression prevailed that oil fired boilers did not require as frequent or as thorough cleaning as coal fired. The efficiencies of oil fired boilers were generally higher than those obtained where coal was used as fuel, due to more perfect combustion with a smaller quantity of excess air, and this improvement was for some time accepted on its face value as the best obtainable. With the increasing use of oil as fuel in the past few years, it was inevitable that detailed tests should be inaugurated of the performance of oil fired boilers with and without mechanical soot blowers.

These tests developed the fact that mechanical soot blowers are absolutely essential to the development of the highest efficiencies of oil fired boilers.

As an example attention is called to the results of the following test by the Pacific Gas and Electric Company:

Test Data Before Using Soot Blower

Time	Temperature		Load
A.M.	Stack	Sup. Steam	Meter
10.15	550	500	4.2
10.30	550	502	4.0
10.45	555	498	4.0
11.00	557	498	4.1

Test Data After Using Soot Blower

Time	Temperature		Load
A.M.	Stack	Sup. Steam	Meter
2.30	485	495	4.2
2.45	485	506	4.0
3.00	485	504	4.3
3.15	485	505	4.2

Test Results	Before	After
Load Meter	4.075	4.175
Steam Pressure Gauge ...	199.5 lbs.	200.75 lbs.
Per Cent. Rating	101.88%	104.38%
Superheated Steam Temp.	495.5 F.	502.5 F.
Stack Temperature	553. F.	483.75 F.

These results show that the soot blowing caused the temperature of the stack gases to fall from 553 degrees F. to 483.75 degrees F., making a difference of 69.25 degrees F. or 13.05 per cent.

"Also the temperature of the superheated steam was raised from 499.5 degrees F. to 502.5 degrees F., a raise of 3 degrees of 0.6 per cent.

"The direct effect of the use of Diamond Soot Blowers is saving in fuel of 3.9 per cent."

The Texas Company, Port Arthur. Texas, found a saving of 5.5 per cent. fuel by the use of mechanical soot blowers and as a result ordered equipment for thirty oil fired boilers. As this company is in the oil producing business, its action is particularly illuminating.

These tests were followed by others at some of the large Western central stations. On one of these, the boiler, a large Stirling, was taken off the lines and the tubes, superheater, etc., washed clean. The boiler was then fired up and an evaporation rate of 37,000 pounds of water per hour and 14 per cent C02 was maintained. At the end of twenty-four hours, the soot blowers were operated and were used for twenty-four periods for the remainder of the test, with the equipment. During these tests, readings were taken at fifteen minute intervals, of the water-rate. C02, draft, oil, and superheat. When using the blowers the flue temperature dropped to 525 degrees and rose to 540 degrees in about fifteen minutes. It ranged around 540 degrees for about sixteen hours and then gradually crept up to 590 degrees at the blowing period, when it again dropped to 525 degrees. This was the regular daily performance throughout the test while using the blowers.

At the end of a seven-day period the boiler was given a final blowing and thereafter operated under the usual plant conditions; i.e., without any cleaning at all. At the end of the first twenty-four hours' run the temperature had risen to 590 degrees, at the end of the week it had risen to 680 degrees, and at the end of ten days had risen to 720 degrees, at which point it seemed to hold. But they were not able to maintain the evaporation rate, which dropped to 34,000 pounds per hour. The saving effected by soot blowers amounted to 6 per cent.

Despite the war emergency, with the constant urge to speed, rather than to thoroughness, the Emergency Fleet Corporation made some very detailed tests of Diamond Soot Blowers before adopting them. These tests were conducted at Burlington, Iowa, under the direction of the Bureau of Mines.

The boiler selected was the Foster Marine Water Tube, and was one of a large number then built by the Murray Iron Works of Burlington. Iowa, for the Power Specialty Company, of New York, for delivery to the Corporation. The tests extended over a period of a number of weeks and covered a wide variety of operating conditions and drafts.

In addition to proving the necessity of soot blowers to economical operation, the tests threw some important light on soot blower construction. For instance, in boilers burning fuel oil, draft conditions are very low, running from .02″ in the furnace up to .08″ in the uptake. If soot blowers were so designed that all nozzles emitted steam at the same time, a curtain or blanket of steam would be ejected into the boiler at high velocity, with the result that it would either put out the fire or materially interfere with the draft. The bad effects of interfering with the draft can hardly be overstated. As a result of such a condition, all of the factors in the operation of the boiler become unbalanced.

This applies to the feed of oil to the furnace, the maintenance of even steam pressure, and the injection of the feed water. In place of a normal, even operation a condition of ebb and flow takes place which may last for an hour or more before conditions again become normal. Necessarily, this entails additional work on the part of the fireman who finds the whole routine and operation of the boiler room upset.

In order to take account of this condition, the soot blower for hollow staybolt boilers is made up in vertical sections, each under the control of its individual valve. This arrangement permits of blowing three or four vertical rows of tubes at one time, thus avoiding all interference with the draft.

On stationary boilers of the horizontal

water-tube type vertically baffled, and vertical boilers, where revolving soot blower units are commonly used, the use of oil for fuel calls for little change in construction. Care is taken in locating the units to be sure that they blow with the draft. In addition, it is sometimes found advisable to stagger or offset the blower nozzles so that they do not all blow in the same direction at the same time. The mechanical soot blower for oil fired boilers is here to stay, and the use of blowers on such boilers is fast becoming as common as the use of blowers on coal-fired boilers.

Specifications for Fuel Oil

The Bureau of Mines has prepared the following specifications for purchase of fuel oil, for the Government, which may, with some modifications, depending upon conditions, be used by engineers generally:

"1—In determining the award of a contract, consideration will be given to the quality of the fuel offered by the bidders, as well as the price, and should it appear to be to the best interest of the Government to award a contract at a higher price than that named in the lowest bid or bids received, the contract will be so awarded.

"2—Fuel oil should be either a natural homogeneous oil or a homogeneous residue from a natural oil; if the latter, all constituents having a low flash point should have been removed by distillation; it should not be composed of a light oil and a heavy residue mixed in such proportions as to give the density desired.

"3—It should not have been distilled at a temperature high enough to burn it nor at a temperature so that high flecks of carbonaceous matter began to separate.

"4—It should not flash below 140 deg. Fahr. in a closed Abel-pensky or Pensky-Martens tester.

"5—Its specific gravity should range from 0.85 to 0.96 at (59 deg. Fahr.); the oil should be rejected if its specific gravity is above 0.97 at that temperature.

"6—It should be mobile, free from solid or semi-soldid bodies, and should flow readily at ordinary atmospheric temperatures and under a head of one foot of oil, through a 4-inch pipe 10 feet in length.

"7—It should not congeal or become too sluggish to flow at 32 deg. Fahr.

"8—It should have a calorific value of not less than 10.000 calories per gram (18,000 B.t.u. per pound); 10,250 calories to be the standard. A bonus is to be paid or a penalty deducted according to the method stated under section 21, as the fuel oil delivered is above or below this standard.

"9—It should be rejected if it contains more than 2 per cent. water.

"10—It should be rejected if it contains more than 1 per cent. sulphur.

"11—It should not contain more than a trace of sand, clay or dirt.

"12—Each bidder must submit an accurate statement regarding the fuel oil he proposes to furnish. This statement should show:

"(a)—The commercial name of the oil.

"(b)—The name or designation of the field from which the oil is to be obtained.

"(c)—Whether the oil is a crude oil, a refinery residue, or a distillate.

"(d)—The name and location of the refinery, if the oil has been refined at all."

JENKINS BROS., LTD., NEW ADDITION

With its spacious interior transformed for the time being into a veritable fairyland of flags, streamers and bunting, the new machine shop for the iron valve division at the Jenkins Bros. plant, 103 St. Remi Street, Montreal, was recently the scene of a very enjoyable social entertainment. Gotten up by way of fittingly inaugurating the opening of this latest addition to the big valve manufacturing establishment, its success was noticeable both as regards the numbers in attendance and the excellent arrangements which characterized it throughout. Certain it is that the 400 or more couples participating, including the management, employees and invited guests, enjoyed every instant of the time from the moment of their arrival until their departure in the "we sma' hours."

Mr. W. F. Trimble, the managing director, after tendering the gathering a very cordial welcome, outlined the provisions made by the Company for the future welfare of the employees under the Group Insurance System, as well as a pension scheme. The hearty applause which greeted the conclusion of the speaker's remarks was evidence of the keen interest and whole-hearted approval displayed by those directly concerned.

A flashlight photograph was then secured of the entire assemblage, after which the festivities began in real earnest The fascination of the euchre tables attracted a goodly number of those present and throughout the evening vied with the dancing floor in the matter of popularity. The latter specially laid for the occasion, was all that the heart or feet of the most particular devotee of the "light fantastic" could desire, its attractiveness being still further enhanced by the stirring music of the Grenadier Guards Band.

Much interest was displayed by those present in a group of photographs showing the steady growth of the institution from the period of its establishment, in 1864 in the United States, and 1906 in Canada, up to the present day. With the increased manufacturing facilities which the new machine shop will afford the Iron Valve Division, the Company will be in a splendid position to handle their steadily increasing business.

At the refreshment counter everything that the inner man (or woman) desired was served in a most generous way. Full justice having been done these, dancing was again resumed and the hour of departure, 2.30 a.m., heralded by the strains of the National Anthem, brought the delightful evening to a close.

NOT THE SAME BARS

In the July 5th issue of Power House on Page 65. there appears an error in the wording of an advertisement of Leonard & Sons Connelly boilers, which although apparent at once to a technical man, might not be so obvious to the boiler purchaser. The error in question is the use of the word crow instead of crown in describing the constructional features of these boilers. The wording is at follows: "Simple in design, no flat surfaces, no stay bolts, no crow bars." This should be "no crown bars." A crow bar, though a useful tool in its place, has no place in the internal economy of a steam boiler.

L. D. Canfield, assistant district service manager at the New York Office of the Westinghouse Electric & Manufacturing Company, was appointed district service manager to succeed L. G. Richards, who has been transferred to East Pittsburg.

W. E. Freeman has been appointed director of commercial training of the Westinghouse Electric & Manufacturing Company.

The following appointments have been made in the Los Angeles district office of the Westinghouse Electric & Manufacturing Company: G. O. Noble, appointed special representative; G. B. Kirker, appointed manager railway division; R. A. Hopkins, appointed manager of the power and marine division.

The Standard Machinery and Supplies are the Canadian representatives of the Waltham Grinding Wheel Company of Waltham, Mass.; J. L. Goodhue Company, Limited, Danville, Que.; and the Clinton Metallic Paint Company of Clinton, N.Y., in addition to carrying large stocks of tool steels, machine tools and other supplies.

Common Sense in Engineering

A Lecture Delivered During the J. E. Aldred Lectures on Engineering Practice at John Hopkins University.

By WALTER M. McFARLAND

THE term "common sense" is used with great frequency, and yet, as you know, with different meanings. Indeed, it is sometimes said that common sense is really very uncommon. To avoid ambiguity, we will attempt a definition as follows: "Common sense" is the application to the solution of problems of one's best experience and judgment without prepossession or prejudice. The qualifying clause is most important, because innumerable cases have occurred where an erroneous decision was reached by men of great ability just because they allowed their judgment and experience to be overruled and biased by prepossession or prejudice.

Possibly the most striking case of this kind, which is known to everybody, is that of the unwillingness of the Syrian general Naaman to take the advice of the prophet Elisha in order that his leprosy might be cured. You remember that the prophet told him to wash in the River Jordan. Naaman's prejudices, however, made him object to this extremely simple cure, and he wanted to know why the rivers of Damascus would not be better. His servant had more common sense than the master, for, as you remember, he said to him that if the prophet had directed him to do some great thing he would have done it at once, and why not follow out this perfectly simple injunction? The common sense of the servant prevailed and the general was cured of his leprosy.

It should also be very thoroughly understood that so far from excluding all the benefits of education and intellectual training, the true meaning of "common sense" assumes these as vital factors. In other words, to praise and emphasize the importance of common sense does not mean to disparage education, but, on the contrary, insists upon it most strongly. On account of the native shrewdness sometimes exhibited by uneducated men there is occasionally a tendency to think that common sense is a gift which can compensate for the lack of education. In fact, the shrewdness displayed by the uneducated men when analyzed will be found to agree entirely with our definition above. They are really keen observers, and have, within their limit, good experience, so that the sound judgment which they display is really a good illustration of common sense. It would be found, however, on test that the field within their judgment could be exercised is very limited as compared with that of the highly-educated engineer.

In discussing the subject of our lecture I propose to follow what is called in the law schools the "case system"; that is, to develop principles by the examination of specific cases. This is usually clearer, more interesting and more satisfactory than to announce abstract principles and then attempt to elucidate them.

A striking illustration of common sense in engineering is the revolution in the use of steam brought about by James Watt, inventor of the separate condenser. The steam engine as invented and developed by Newcomen was doing useful work, but it was very generally realiezd that it was exceedingly wasteful. As you will remember, the engine worked at atmospheric pressure, steam being admitted from the boiler underneath the piston, which was slightly overbalanced so that it would then ascend to the top of the stroke. A spray of cold water was injected inside the cylinder, which condensed the steam, producing a partial vacuum. The pressure of the atmosphere caused the descending stroke of the piston. It seems to us now that it ought to have been perfectly evident that, as the cylinder was necessarily chilled in causing the condensation of the steam, there would inevitably be great initial condensation of the newly-admitted steam before the temperature could be raised sufficiently to permit the steam to fill the cylinder, and that, in consequence, it was almost obvious that the condensation should take place in a separate vessel. It was, however, not until the Newcomen engine had been used for nearly seventy years that this revolutionary change was made by Watt, who was led to it when making repairs to the model of a Newcomen engine at the University of Glasgow. It must not be supposed because Watt was an instrument maker that he was not a scientific man. He was a friend and pupil of Professor Black of the University, who is, perhaps, best known as the discoverer of latent heat, and it is probable that this scientific knowledge led him to the careful study of conditions which resulted in the invention of the separate condenser.

As you know, Watt made other great inventions connected with the steam engine, so that, speaking generally, up to the time of the invention of the steam turbine the improvements made by later inventors were almost entirely in matters of detail rather than of principle. It is very interesting to note in this connection that, in spite of his shrewd common sense in his earlier inventions, Watt's prejudices led him to oppose very strongly the use of high pressures. Doubtless it was because the success of his early work in connection with very low pressures that he was so prejudiced, but it illustrates the point that, notwithstanding his wonderful ability, he did not use common sense with respect to the higher pressures.

As we now look back over the further improvements in the steam engine, we are greatly surprised to find that it took so long to apply fully the principles which Watt had announced of endeavoring to keep the cylinder as hot as the entering steam. Of course, it is impossible to do this completely when the cylinder head and passages have just been in communication with the exhaust at a much lower temperature than the incoming steam. Nevertheless, it should have occurred to a careful analyst of the conditions that division of the expansion into two or more stages in separate cylinders would make the temperature variation in each particular cylinder very much less and would thereby conduce to economy. Long after the compound engine, with the expansion in two stages, had become quite common this point was not fully appreciated. Indeed, as late as 1880 Rankine's Treatise on the Steam Engine, then considered the best work on the subject, distinctly stated that, so far as economy in the use of steam is concerned, it made no difference whether the expansion occurred in one, two or a dozen cylinders. After the principle was thoroughly appreciated and when improved materials permitted the construction of boilers for much higher pressure, the introduction of the triple expansion and quadruple expansion engines came almost as a matter of course.

For a number of years I had the pleasure of frequent association with that great mechanical genius, George Westinghouse, the inventor of the air brake, while I was an officer of one of his companies, and on one occasion I heard him tell the story of the final step in his invention of the air brake, which is a splendid illustration of common sense. He was led to invent a power brake of some kind by his knowledge of the inadequacy of the means then employed, and his first idea was of one operated by steam. He fully realized the disadvantages due to condensation, but thought at first that these must be accepted. He had devised the brake cylinder and rigging under the car and was nearly ready to experiment. He was a reader of the "Scientific American," and one day the new issue contained a description of the mechanical features of driving the Mont Cenis tunnel under the Alps. This described the rock drills driven by compressed air, and incidentally stated that, at the time the article was written, the heading of the tunnel where the drills were working was about a mile from the air compressors outside the mouth, and that there had been no trouble on account of this distance between the generation and application of the compressed air. He at once realized that here was the ideal fluid for transmitting his power.

If it was satisfactory for the rapid-working pistons of rock drills at a distance of a mile from the compressor, it certainly would be satisfactory in the brake cylinders under the cars at a distance measured by hundreds of feet. Thus was born the air brake, which, with its subsequent developments and improvements, has probably done more for the safety of high-speed railroading than any other single invention ever made.

The first great improvement was again a beautiful illustration of common sense. In the beginning the idea was to apply the brakes on all cars practically at the same moment so as to stop all the cars at the same time. After this had been successfully accomplished and people began to rely thoroughly on the brake, an accident occurred when some cars broke from a train on an incline, which left nothing but the hand brakes to stop the descent of the detached cars. Up to that time, when it was desired to apply the brakes, pressure was admitted to the train pipe, and so to all brake cylinders. Common sense suggested to Mr. Westinghouse that if it could be arranged to keep pressure on the train pipe as the normal condition, with the release of his pressure to set the brakes, then if any cars became detached the brakes on the cars would be automatically set. To carry out this idea he invented what is known as the "triple valve," which, in connection with a reservoir of compressed air under each car, fully accomplished this purpose of complete safety. The triple valve fulfils the three purposes of filling the reservoir under the cars, admitting the air from the reservoir under each car to the corresponding brake cylinder for the application of the brake, and exhausting the air from the brake cylinder when the brakes are to be released.

Nearly all of Mr. Westinghouse's many inventions were illustrations of his splendid common sense, and they were evolved from existing methods to meet conditions which arose in the application of the mechanism. One of these inventions was made while I was with him, and I knew many of the details, so that the story will, I believe, interest you.

When Sir Charles Parsons had invented and developed the steam turbine until it became reasonably economical, Mr. Westinghouse secured the patent rights for the United States and proceeded to develop it chiefly in connection with electric applications. As the power and size of the turbines increased it was found that there were difficulties due to the expansion of the material accompanying temperature changes in such long structures. As you are aware, the Parsons turbine is of the "reaction type." De Laval, a Swedish inventor, had developed a different kind of turbine, known as the "impulse type." In this latter the steam is expanded in special nozzles before entering the blades so as to reach them with a very high velocity and greatly reduced pressure. Familiar as you are with the properties of steam, you know that this reduction in pressure is accompanied also by a reduction in temperature. Mr. Westinghouse was familiar with both types of turbines, and it struck him that the way to obviate the difficulty due to this expansion of the material was a form of compounding turbines somewhat analogous to what has been done in the steam engine. Consequently he bolted to the casing of the reaction turbine a small independent but connected casing containing a few rows of impulse blades and reduced the pressure from the initial figure of about 200 pounds to about 75 pounds when it entered the reaction blading. This smaller casing was free to expand without affecting the larger ones. Along with this he introduced what he called the "double flow" principle by practically puting two reaction turbines in the same casing with the higher pressures in the center and the exhaust connection at the ends. This solved the difficulty, and this method in various forms is the one now used in all the large turbines of to-day.

The Diesel engine is a most interesting subject for consideration by engineers on account of its remarkable thermal efficiency of some 30 per cent., which is about double that of good reciprocating steam engines. In fact, marine records of good average practice are one-half pound of oil per brake horse-power for the Diesel engine and about one pound of oil per indicated horse-power for a good reciprocating engine plant.

More than twenty years ago Dr. Diesel believed he had perfected his engine, and many engineers who had studied his work went so far as to say that the steam engine would be obsolete in a few years and would only be found in museums. For a considerable interval thereafter little more was heard of it until about ten years ago. Possibly it was because the basic patent expired at that time and possibly because the engine had been worked out commercially; but at all events the technical papers were full of accounts of Diesel engines being fitted to numerous vessels, and again there was the same prediction that the steam engine would soon be displaced. As a matter of fact, the extent of the use of the Diesel engine has been a great disappointment to its advocates, and at the present time relatively few are now being installed in new vessels.

As information was published of the details of these engines, it became apparent that they were all designed with a horse-power per cylinder which did not exceed 250 to 300. At first there were a great many vague statements that experiments were in progress with cylinders to give from 1,000 to 4,000 horse-power per cylinder. In one such experiment there was an explosion with serious consequences. At all events, for some time there has been no talk of these more powerful cylinders. It will be realized at once that if any prime mover is to be used for large powers it must be capable of construction in large units. The reciprocating engines of the SS. "Olympic" have cylinders of 4,000 horse-power each, so that a single four-cylinder engine develops 16,000 horse-power. A Diesel engine developing only 250 horse-power per cylinder would, of course, require sixty-four cylinders to give the same power. The enormous multiplicity of parts to be looked after and kept in adjustment, even if this were individually easy, would be sufficient to prevent such use, while, in fact, the Diesel engine requires unusual care and attention to keep it in good order.

The question naturally arises, "Why is it that the Diesel engine cannot be built in large sizes?" And here common sense gives us the answer quite simply. Like all other internal combustion engines, the Diesel engine requires that the cylinders be water-jacketed so as to keep the barrel sufficiently cool to permit the proper working of the pistons. The pressures carried are quite high, from 700 to 1,000 pounds per square inch, requiring a thick cylinder even for a power of 250 to 300 horse-power. The fact is that this thickness is evidently about the maximum which will permit the interior cylinder wall to be kept of a sufficiently low temperature for satisfactory working. It happens that cast iron is by far the best material which has ever been found for the cylinders of quick-moving reciprocating engines. If a material could be found which has all the fine wearing qualities of cast iron with several times its thermal condustivity, then we might expect Diesel engine cylinders of greater power; but until that comes, or there is some other radical invention, the nature of which is not now apparent, the Diesel engine seems limited to small powers.

There is another aspect of this case where that form of engineering common sense which we may call the "commercial side of engineering," comes in very prominently. Popular descriptions of Diesel engines have always laid stress on their elimination of the boilers, with a consequent saving in space. They have, so far as I know, carefully avoided a comparison of weights. Through the kindness of a friend who is a Chief Engineer of a large shipbuilding company, and who had made a very careful comparative study of Diesel engines and steam turbines for certain vessels, I have been enabled to secure reliable data on this point of weight. You will perhaps be surprised to learn that for about 3,000 shaft horse-power the Diesel engine installation weighs nearly double the steam plant, including turbines, bodilers and auxiliaries. As might be expected, there is also a very great difference in the first cost, the Diesel engine exceeding the steam plant by over 50 per cent. My friend made up a very careful comparison of the operation of the two vessels, identical except machinery, extending over a year, with the net result that the earnings based on first cost worked out to almost exactly the same percentage.

This discussion emphasizes the impor-

tance of remembering that thermal economy in an engine is only one of the factors to be considered in determining whether to be considered in determining the matter may be put in this way: every commercial enginering product must show a profit on the investment. This is just as important as high efficiency, adequate strength or admirable design. Failure to show a profit will offset the greatest merit in these other features.

A striking illustration of common sense in engineering came under my personal observation when I was in the naval service, and is worth careful study.

The early vessels of what was then called our "new navy," designed from, say, 1885 to 1890, were fitted with independent air pumps for the main engines. There were usually two air pumps driven by a small two-cylinder compound engine of the crank and flywheel type, the connecting rods of the pumps ataching to the same crank pins as the conecting rods of the engine. While an excellent design from the standpoint of a steam engine for ordinary purposes, there was a serious defect in these engines which was not realized until after they were put in use, due to assuming that an engine which would be satisfactory for ordinary purposes would be equally satisfactory for operating an air pump. In practice they proved very unsatisfactory. If they were given sufficient steam to handle a heavy load then they would run away with a light one. If they were adjusted for the light load then they would stop when a heavier load came on them. In practice this required a man to give them almost constant attention, which was very undesirable.

As soon as this trouble was recognized, the designers at the Navy Department and in various shipyards began to scheme methods of remedying the difficulty, and various methods were tried without success. Meanwhile, the makers of standard twin-cylinder air-pump work somewhat on the lines of their direct-driven water pumps, and this type of air-pump had proven a great success. It could be run at any desired speed, depending on the output of the main engine, and required practically no attention. After this pump became available it was used exclusively, but the older ships remained with the unsatisfactory air-pumps, and it was highly desirable, if possible, to correct the defect without replacing the air-pump engines. Finally Chief Engineer Bailey (now Admiral Bailey), then Chief Designer in the Bureau of Steam Engineering, took up the problem. I knew him intimately, and he gave me the details of his solution of the rifficulty.

Recognizing that the direct-driven air-pump was unsatisfactory, his first step was to find the points of difference between this type and the air-pump engines previously used. The compound engine had been designed with steam ports of the usual proportion, namely, 10 per cent. of the piston area. In the direct-driven type the ports were only about 3 per cent. of the piston area. In the direct-driven type the port opened wide at the very beginning of the stroke and stayed wide open until almost the very end. The valve gear of the compound engine was arranged, as is usual in such engines, to cut off at about three-quarters stroke; and, being driven by an eccentric, opened gradually and closed gradually, being wide open for only a short time. Mr. Bailey's conclusion was that the direct-driven pump builders had wisely decided to make the port so small that, if the load on the pump became very light and there was any tendency to run away, the steam would be wire-drawn by the small port enough to prevent any excessive speed. On the other hand, if a very heavy load came on the pump, the port being wide open would permit the steam pressure to come in to its full extent so that the piston could not stop. With the existing conditions of the older plant he must continue to drive the valve by an eccentric, but he knew a valve seat could be fitted with ports about 4 per cent. of the piston area, and a new eccentric and valve could be fited to work without lap or lead so that the port would open at the beginning of the stroke and would be open to some extent at all times. This change was made, and the result was complete satisfaction, as I can testify by personal observation from having been on a vessel where the change was made during my service. I consider this one of the best illustrations of common sense in engineering that I know. The change was not serious, was comparatively inexpensive, and it accomplished thoroughly the aim of the designer.

It was emphasized in the beginning of the lecture that common sense does not mean lack of education or absence of fine professional equipment. Indeed, these are vitally necessary, and the story which I am about to tell you will show that a well-equipped man is able sometimes to give an opinion which to the uninformed seems almost uncanny.

An accomplished naval engineer, who was one of my instructors at the Naval Academy, once told us of an amusing experience with reference to estimating the speed of a ship. He was attached to a vessel on the Asiatic Station, and during his service a new passenger vessel came out from England which was reputed to be very fast for those days. The two vessels happened to be in port together, and when passing the liner one of the officers remarked that the vessel could make sixteen knots. My friend looked at the vessel a little while and said: "That is impossible, and her speed is probably not over fourteen knots." He was at once asked how he could be so sure, and he replied: "I can tell by the size of the smokepipe." This led to jeers from some of the party, who really thought the answer was a joke. Those of you who have studied boiler design at all will probably know at once that there was a real foundation for his statement, and for the benefit of the rest I will give this analysis of the way in which he formed an opinion.

In a well-designed boiler installation there is a definite relation between the cross sectional area of the smokepipe and the grate surface. It was before the days of forced draft, so that he knew the amount of coal that could be burned per square foot of grate surface, and, with the average economy of the machinery, the horse-power which would result. He was a man who had made a careful study of the propulsion of vessels, and knew roughly about what horse-power would be needed to drive a vessel of the size in question at a speed of sixteen knots. He could estimate fairly the diameter of the smokepipe, and with this as a basis, a hasty mental calculation showed that the power which the machinery could develop was very much less than would have been necessary for sixteen knots. If any of you have had the opportunity to observe the trans-Atlantic steamers you will appreciate this point about the smokepipe by the actual conditions of some of the great liners of today. The SS. "Mauretania," which is a vessel of about 70,000 horse-power and twenty-five knots speed, has four huge funnels, while the White Star liners of nearly the same displacement have only two moderate-sized funnels, but they make only about 16 knots. So you see that a man who is well posted professionally in marine matters could really form a fair judgment as to speed of a vessel by the size of her smokepipe.

To be Continued

REMARKABLE ELECTRIC WELDING

One of the trickiest problems in welding is to join the ends of steel tape so as to form a continuous length for winding round electric cables to protect them against mechanical damage. This problem has been successfully solved by a British firm, which has devised an electrical machine for the purpose. One end of the tape is held in a fixed jaw and the other in a movable jaw, and when the weld is being made the two ends are brought together with a carefully controlled and increasing pressure up to the completion of the weld. Showers of sparks are thrown out as the metal burns away until the whole width of the join is in a plastic state: then the final pressure squeezes out all the burnt metal and makes a perfect weld. The thickened metal at the joint is either hammered flat or ground off.

Coal Board Issues Order.—The Railway Board at Ottawa has issued an order which prohibits the exportation of coal from any Atlantic, St. Lawrence River, or Gulf port of Canada, excepting to the United States or Newfoundland. The order becomes effective on and after August 1st, and was issued after the consideration of information gained from the United States Inter Commerce Board.

Developing High Overload Capacities

Particulars of Tests Run on Water Tube Boiler with Horizontal Baffling to Determine Efficiencies at High and Low Ratings.

Modern industrial boiler plant practice at present shows a marked tendency toward the use of larger and more efficient units in order to avoid the labor troubles, shut-downs, and standby losses experienced with low capacity and uneconomical equipment. In some instances, this is achieved by rebuilding the boiler house, installing up-to-date high duty boilers, and by introducing the proper machinery for handling coal, ashes and feed water.

In one of the largest textile mills, for example, five 950 H.P. horizontally baffled water tube boilers and superheaters set with underfeed stokers have been installed, to replace seventeen 250 H. P. and four 275 H. P., a total of 21 fire-tube boilers equipped with hand fired grates. The water-tube boilers have been in operation for about two years under conditions of unusually severe and continuous service and have fully demonstrated through satisfactory performance the advantages of units of this size and type. Whereas 10 firemen, 5 water tenders, 2 repair men and 1 foreman were required formerly, the present force consists only of two men, one to watch the boilers and the other to operate a coal crane.

The present paper describes briefly a series of four tests conducted on one unit of the installation to ascertain whether an arrangement of the horizontal baffling suitable for attaining high capacities would prejudice the efficiencies obtainable at lower ratings.

The tests were run under the usual working conditions prevailing in the plant in order to get results which would represent the commercial performance to be expected in industrial service from large stoker-fired boilers of this type. Nothing was "polished up" in order to get record-breaking results. At the time of the trial, the boiler tested had been in continuous service for three and one-half months.

All of the plant load, in excess of the capacity developed by the unit under test, was handled by three of the other boilers operated at moderate rating by the regular boiler room force.

The fuel burned was taken at random from the large tonnage in storage at the plant and comprising many deliveries from various sources. The results of analysis indicated that this was only a fair grade of low-volatile Pennsylvania coal, typical in quality of the vast quantities of similar fuel delivered to the New England mills during the past two years.

The boiler tested was a standard Heine horizontally baffled boiler set as shown Fig. 1. The arrangement of baffling should be particularly noted. It is simple and inexpensive to repair, replace or to change in location. Such modifications are often advisable if high efficiency is to be maintained with different furnace conditions resulting from a change of fuel or operation. The principal dimensions of the boiler are as follows:

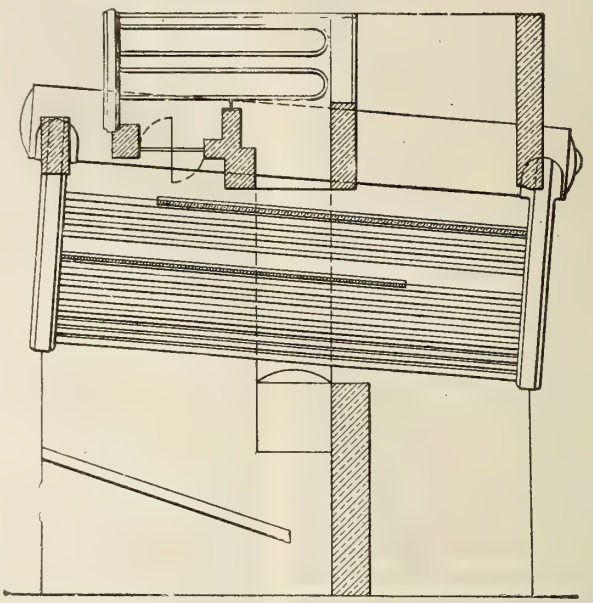

FIG. 1—950 H.P. HEINE THREE DRUM WATER TUBE BOILER EQUIPPED WITH SUPERHEATER.

No. of steam drums	3
Diameter of steam drums	42 in.
Length of steam drums	20 ft. 9 in.
No. of tubes	551
Diameter of tubes	3.5 in.
Length of tubes	18 ft.
Water heating surface	9,500 sq. ft.
Superheating surface	633 sq. ft.
Grate surface, including dump grate	147.4 sq. ft.
Ratio of water heating surface to grate surface	64.5 to 1
No. of Riley stoker retorts	0

A thorough examination of the boiler, superheater, setting and stoker was made before and after the tests were run. The boiler was found to be free of all leakage, and deposits of soot or slag on the heating surfaces. There was some scale in the tubes which increased in thickness from nothing in the upper tubes to 1/16 in. in the lower ones. The brickwork of the furnace, setting and superheater was in good condition. The baffling was intact and tight. The Riley Stoker was in excellent mechanical condition throughout the tests.

The method of conducting the boiler trials was that prescribed by the A.S. M.E. Code. All instruments and scales were compared with standards. The calibration of the water measuring tanks was checked by independent observors.

The coal was weighed by a sealed scale carrying an overhead hopper of 2,000 pounds capacity, from which it was transferred as required through a chute to the stoker hopper. The scale was provided with a self-registering beam. Duplicate tickets were made at each weighing. The coal analysis, Table 1,

on samples representing the entire quantity of refuse as weighed worked down in the usual manner. At this point it may be well to direct attention to Tables 1 and 3, and to the discrepancy in the percentages of moisture in the coal for Tests 1, 3 and 4. The values given in Table 3. with the exception of that for Test No. 2, are correct for coal as fired. They were determined by drying representative samples of coal during the tests. No determination of moisture content was made during Test No. 2, but the analyzed percentage was accepted as correct. The samples collected for analysis, (Table 1) dried somewhat during the working down process. If a sample for Test No. 2 had been dried out, it probably would have shown a slightly higher moisture content than 1.61 per cent. This greater value would have increased the efficiency for Test No. 2, and raised it into line with the values for Tests Nos. 1 and 4, as shown by the dotted curve of Fig. 2.

Feed water was measured in three carefully calibrated tanks holding an aggregate of 9,128 pounds of water at 130 deg. F. The test boiler was provided with an independent feed pump and piping. Hot and cold water were available at the measuring tanks enabling the close maintenance of the feed water temperature.

Every precaution was taken in the feed and blow-off piping to insure the measurement of all water entering the boiler and to guard against any leakage.

The coal consumed and water evaporated were determined for each hour of the test to obtain the approximate rating developed. The rating was also observed by means of a General Electric indicating flow meter.

Readings of pressure, temperature, draft, etc., were taken at 15-minute intervals. Analyses were made for C02, C0 and 02 in the furnace flue gases.

Fires were cleaned one hour prior to starting all tests. Especial care was exercised to duplicate the conditions of the fuel bed at the beginning and end of all trials.

Tubes were blown every six hours during the 24 hour test.

The complete data for each test are given in Table 3. In judging the performance results obtained, several important factors should be considered. The coal burned was not a high grade selected fuel but had a fairly high ash content and produced a troublesome clinker at high rates of combustion. The results as obtained with this fuel should therefore be considered as most creditable. The uniformity of the test conditions was materially affected by the variable operation of the three other boilers in service, all supplying steam to a common system. The limitation of capacity performance was entirely due to the inability of the stoker to handle and dispose of the troublesome clinker produced.

The data show that high overload capacities can be developed with this type of boiler and arrangement of baffles. The efficiency characteristic of the boiler and stoker is drawn in Fig. 2. The point corresponding to Test No. 3 is open to question, because the coal used contained more ash than the coal of the other tests. Since the resulting clinker interfered noticeably with the management of the fire at the high rating obtained, this may well account for the low efficiency of Test No. 3. The dotted curve probably represents the true characteristic of the boiler when burning coal of the quality used as long as it can be worked through the stoker. If the efficiency of Test No. 2 were raised slightly by alteration of the moisture content, as mentioned previously, it would agree closely with the dotted curve. The excess temperature of the gases from the boiler as

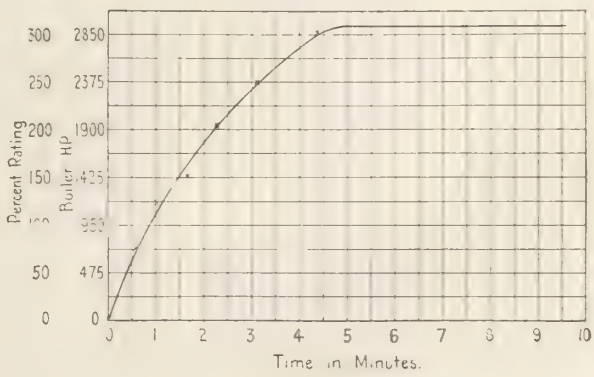

FIG. 4—CURVE SHOWING HOW RAPIDLY THE HEINE BOILER CAN TAKE UP AN OVERLOAD.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

THE elastic limit of the material has an important bearing on its performance in service. The Ontario regulations specify that the elastic limit must be not less than half the tensile stress, and the tensile stress is placed at between 55,000 to 65,000 lbs. per square inch. This means that up to a pull of 27,500 to 32,500 lbs., according to the ultimate tensile stress, the metal will resume its original shape after the load is removed. Above that amount of stress the metal will retain a permanent set, or in other words, will be stretched beyond its original length when the load is removed. In order that the material may possess sufficient ductility, the regulations require that a test piece 8 inches in length shall stretch 22% of its length before breaking.

That is $8 \times \frac{22}{100}$ or 1.76 inches.

Plates that are to be exposed to the action of the fire when in service will have a slightly lower tensile stress and a greater ductility than those which are not exposed to direct heat. The tensile strength is placed at between 55,000 and 65,000 lbs. per square inch, because that is about the limit of strength that can be obtained without sacrificing something of the elastic qualities of the material. The object of obtaining high tensile strength is, of course, to enable thinner plates to be used, which means a saving in first cost. There is, of course, some slight advantage in heat transfer, but it is so slight as to be negligible in the ordinary limits of plate thicknesses. The reduction possible in weight and therefore first cost of plates possible by using material of a higher tensile strength is more than offset by the other undesirable qualities which accrue, chief of which is loss of ductility due to a higher sulphur and phosphorus content. It is hardly within the scope of these articles to go into this question of the chemical analysis of steel, but the foregoing will suffice to give the reader a general idea of the qualities necessary in the material the plates of a boiler are made of.

We have seen that the cylindrical form of boiler is the next best that we can get to the sphere. As we cannot roll the cylinder all in one piece the next point to aim at is to make the joint where the two edges of the plate are joined together, as nearly as possible equal in strength to a solid plate. The working pressure of the finished boiler will be determined by its weakest part, and the object of the good designer is to get the strength of all portions nearly uniform. There have been many boilers built with a shell capable of carrying 100 lbs. per square inch, while the staying of the heads was only fit for a little over half that. The writer has come across many instances where the boiler seems to have been put together without any regard for design at all, and with a different capacity for resisting pressure at each constituent part. However, it is not possible now in Ontario to build these freaks, and some day a uniform law for all the provinces will come about.

The Starting Point

If you were suddenly requested by the owner of your plant, or a prospective plant owner, to give him the size of a boiler to evaporate a certain quantity of water per hour at a certain pressure, how would you proceed to answer him? Would you make a wild guess, or would you ask him to give you a few moments to figure it out? Would it then occur to you to enquire under what conditions this boiler had to evaporate this quantity of water, such as with natural or forced draught, hand or mechanical stokers, low grade or high grade coal, with feed heaters or without? Having got the information, what point would you start from to make your calculations? There is one factor that fundamentally governs the capacity of any boiler, and which is the logical starting point, and that is, the quanity of coal which can be burned per square foot of grate per hour. Upon that quantity everything else depends. If, owing to a restricted grate, or lack of draught, the necessary amount of coal cannot be burned, the evaporation cannot be obtained. If you have a properly proportioned grate and setting, for the requirements, it is then a question of operation to get the results. From this we can see that we have a starting point from which we can build up the complete apparatus.

Capacity of Boiler

The capacity of a boiler, of its ability to evaporate water, depends as we have seen, on the grate area. However, it is necessary to have a definite unit, to compare or to specify sizes. The recognized standard boiler horse power is the capacity to evaporate 34½ lbs. water per hour from and at 212 deg Fahr. This means water at 212 deg. Fahr. turned into steam at 212 deg. Fahr. This is a definite performance, and demands the absorption of a certain number of units of heat.* The Ontario Act gives the quantity of water as 34 lbs., but this is probably just to show that the authorities have a mind of their own. The accepted value, as laid down by the committee of the American Society of Mechanical Engineers, is 34½ lbs., and this is the figure generally used. However, in writing on examinations, always use the standard of the authority that is conducting the examination.

The rating of a boiler by heating surface is of little value as an indication of its capacity, but is useful as a commercial comparison. The standard laid down by the Ontario Act is 15 square feet of heating surface per horse power, for a horizontal return tube boiler, 12 square feet for locomotive boiler, and 10 square feet for water tube boiler. These figures are used in rating plants or certificates, and are useful for that. The only real measure of a horsepower is, nevertheless, the quantity of water evaporated, or in other words, the amount of heat absorbed.

If then, we are called upon to design a horizontal return tube boiler of 100 horse power capacity, we know we must figure on the evaporation of 34½ lbs. water per horsepower per hour from and at 212°. However, we must know some more details, as for instance the pressure the boiler has to work at, and also the average temperature of the feed water. We will assume that we are to use natural draught. To evaporate 34½ lbs. water from 212° to steam at 212° we must furnish 970 heat units per pound

If we have feed water at a temperature of 60° and steam at 125 lbs. gauge pressure we have a different number of heat units to furnish. We shall have to first raise the water from 60° to 212° and then furnish enough additional heat to make steam at the temperature corresponding to 125 lbs. gauge pressure. This is 353° F. so that we have to furnish the difference in temperature of 60° and 353° and also a certain quantity known as the latent heat, which we will explain fully when we consider steam. This for the pressure we are considering is 867 heat units so that we have to supply altogether 353 + 867—60 = 1220—60 = 1160. This is $\frac{1160}{970} = 1.195$ time the amount needed to change water at 212° to steam at 212°. Suppose now a feed water heater is to be installed that will raise the feed water to 200° before entering the boiler, we will have to add only 353+867 — 200 = 1220—200=1020, which is considerably less, in fact just $100 - \frac{1020}{1100} \times 100 = 12.1$ per cent. less.

We will proceed on the assumption that there is no heater, and that for each

pound of water evaporated we require 1160 heat units. The total number of units required for 100 horsepower at the standard measurement will be $100 \times 345 \times 970 = 3{,}346{,}500$ heat units. However, as we are to produce steam at 125 lbs. pressure this quantity of heat will make only $\frac{970 \times 3450}{1100} = 2884.9$ lbs. of steam per hour. This quantity of steam would supply a simple Corliss engine of about 100 h.p., or an automatic engine of about 70 h.p., a steam turbine of 240 h.p., or a compound condensing Corliss engine of about 130 h.p. From this you can see that a boiler of a certain rated horsepower may be able to drive an engine of much higher h.p. or unable to drive one of much lower horsepower, according to the consumption of steam per horse power per hour of the engine. This shows again that by measuring capacity of boiler in terms of evaporation we are on a solid basis.

We have therefore to consider supplying 3,346,500 B. t.u. per hour, to the boiler. To do this, we must have fuel, and we must know beforehand about what heat value the fuel possesses. This will vary with the locality it is obtained from, but we can be safe in allowing for a coal with heat value of 11500 B.t.u. per pound. If all this heat could be transmitted to the water it would be fine, but we know that with ordinary hand firing and natural draught conditions we shall do well if 60 per cent. of the heat is usefully employed. That means that each pound of coal is only good for $\frac{11500 \times 60}{100} = 6900$ B.t.u. per pound. We must therefore make provision for burning $\frac{3{,}346{,}500}{6900} = 485$ lbs. coal per hour. This is found, as can be seen, by dividing the total heat required by the heat value of the coal per pound, after making the correction for efficiency.

We can reach the same result in another way. We have seen that the total heat in a pound of steam at the specified pressure and temperature it 1160 B.t.w. The heat in a pound of coal, allowing for 60 per cent. efficiency is 6900. Then each pound of coal will make $\frac{6900}{1160} = 5.9$, say 6 pounds of steam. Now, as we must produce 2885 pounds of steam per hour to satisfy the rating, we must burn $\frac{2885}{6} = 480.8$, say 481 pounds of coal per hour. This evaporation corresponds to an evaporation per pound coal of 7.05 lbs water from and at 212°, for the ratio of heat required from and at 212° to that required for water at 60° to steam at 125 lbs. pressure is as 970 : 1160 which is 1.195, and this multiplied by 5.9 gives 7.05.

It is possible with good draught conditions to burn from 12 lbs. to 16 lbs. coal per square foot grate surface per hour. To allow for adverse conditions we will take the lowest figure. We must then have $\frac{480}{12} = 40$ square feet grate surface. Now, we have seen that for this type of boiler the heating surface is 15 square feet per horse power, or a total heating surface of 1,500 square feet. This gives a proportion of heating surface to the grate surface of 1,500 : 40 :: 37.5:1. This is a rather high proportion as some makers allow as low as 30 to 1, while it may range as high 40 to 1. We have allowed very conservative figures in our estimates of the heat value of coal, and efficiency of boiler, so that the grate surface we have arrived at is somewhat high, as compared with practice. In proportioning grate surface, however, it must be remembered that if coal is good and combustion conditions favorable, it is a simple matter to shorten the grate, but if the grate is too small to begin with, it is a difficult mater to enlarge it.

If we then decide to keep the grate area at 40 spuare feet, we can work from this to obtain our other dimensions. The square root of 40 is 6.324. We can therefore take 6 feet as the width of our fire grate, and dividing 6 into 40 we get 6.66, which is about 80 inches. This would require two sets of bars each 40 inches long. This is not too long a grate for easy working. Having determined tentatively that we have a grate six feet wide by 6 feet 8 inches in length, we can now go into the question of the size of boiler necessary to get the requisite amount of heating surface.

Heating Surface

The heating surface in a horizontal return tube boiler consists of half the shell, and the outer surface of all the tubes. The ligaments between the tubes in the heads are such a small percentage of the total area that they may be neglected as far as heating surface is concerned. We see therefore, that diameter of shell, length of shell, and diameter and number of tubes are the deciding factors governing the amount of heating surface. We can make a formula expressing this, as follows:

$$\text{H. S.} = \frac{D \times 3.1416}{2} \times L + d \times 3.1416 \times n \times L$$

$$\text{or H.S.} = \frac{L\ D\ \pi}{2} + \pi\ d\ n\ L$$

where D = Diameter of shell feet
L = Length of shell feet
d = Outside diameter of tube
n = Number of tubes

Our firegrate is 6 feet wide, so we can assume this diameter for the boiler. The tube area in a horizontal boiler is usually taken as about 1-7 the grate area, though if the fuel to be burnt is anthracite, a smaller amount will do, from 1-9 to 1-10. If we allow 1-7 tube area to grate area, we shall require $\frac{40}{7} = 5.714$ or nearly 5¾ square feet. We can use 3-inch, 3½-inch or 4-inch diameter tubes, as may be convenient. The inside diameter of a standard 3-inch boiler tube is 2.732 inches, of a 3½-inch tube 3.26 inches, and of a 4-inch tube 3.732. The internal areas in square feet are respectively .0422, .058 and .076. Then the number of 3-inch tubes required would be $\frac{5.75}{.0422} = 136$. The number of 3½ tubes would be $\frac{5.75}{.058} = 99$ and of 4-inch tubes would be $\frac{5.75}{.076} = 76$.

The size of tube used is a matter of the individual designer's taste. Some claim that a smaller tube and a greater number allow of a better distribution of the gases, and thus a better transfer of heat, while others claim that small tubes are more difficult to keep clean, and do not allow of such good circulation as a less number of larger tubes. The tendency is to use a larger tube, and in boilers of the size we are considering the 4-inch tube is generally favored. We have thus arrived at an approximate number of tubes of a certain diameter, and must now determine the length. A tube should not exceed 60 times its length in diameter, which in this case is 60x4= 240 inches, so that our boiler must not be more than 20 feet long.

The heating surface as we have seen is equal to

$$\frac{L\ D\ \pi}{2} = \pi\ d\ n\ L$$

We have now D = 6 feet, d = .3 feet and n = 76, so we can substitute figures and the equation becomes

$$\begin{aligned} 1500 &= L \times 3 \times 3.1416 + 76 \times .3 \times 3.1416 L \\ &= L(3 \times 3.1416 + 76 \times .3 \times 3.1416) \\ &= \pi L(3 + 76 \times .3) \\ &= \pi L(3 + 22.8) \\ &= \pi L 25.8 \\ L &= \frac{1500}{\pi 25.8} \\ L &= 18.5 \end{aligned}$$

So we get a length of 18.5 feet, which we may accept as being pretty nearly correct. We have, therefore, arrived at the leading dimensions of our boiler, which we may use in the meantime, although it may be necessary to make some modifications when we come to lay it out. As a boiler of this size is required to have a manhole in the front head 12x16 inches clear, we may have to leave some tubes out to allow for this. However, we shall at present, go into the question of the size of plate and type of joint of which the shell must be formed, and after that is settled, we can lay out the tube plate and settle finally the pitch and number of tubes and location of the stays in the head. We will take up the subject of strength of shell and riveted joints in the next issue.

*The British thermal unit is the amount of heat required to raise one pound of water one degree Fahrenheit at its maximum density. Latent heat is the heat required to effect a change of state of

a body. Water at atmospheric pressure and 212° temperature, requires the addition of 970 B.t.w. to turn it into steam at atmospheric pressure and 212° temperature. These 970 do not show on the thermometer or in any way except in changing the nature of the water, and are therefore called the "latent heat." Heat which can be measured is called sensible heat.

CATALOGUES

We have received Bulletin No. 6 of the Norwalk Iron Works, describing and illustrating their refrigerating plants. The bulletin shows motor, belt, gasoline engine driven and chain driven sets. The sizes illustrated are from quarter ton to one ton capacity. These machines are specially suitable for stores, warehouses, etc., where perishable goods are stored. The quarter ton machine is delivered with a full charge of ammonia, and under proper operating conditions the cost of ammonia should not reach more than $5 a year. The same manufacturers furnish a machine for domestic refrigeration, these machines being electrically driven, and so arranged that the same valve which turns on the condensing water supply, also operates the starting switch. This means that it is impossible to start the machine without having the water on. The act of stopping the machine also turns off the water. The space required by the machine is 36 inches by 18 inches by 26 inches in height.

The Buffalo Forge Company have issued Catalog No. 700, describing their heating, ventilating, and humidifying apparatus. This is a most interesting publication, as it is not only a catalogue, but a valuable text book on these subjects. Examples of psychometric charts and humidity charts are given, besides considerable information on the theory of heating and ventilating. Illustrations of different installations in schools and public buildings are included, as well as industrial establishments including pulp mills, railway round houses and food storages. The apparatus itself is clearly described and illustrated. The book will be found a valuable one for the chief engineer to have at hand for purposes of reference when heating problems occur.

The Yarnell Waring Co., have issued a folder describing their Yarway Pipe Joint and Yarway Holtite Pipe Clams, which shows clearly the method of applying these accessories. A price list is included, and particulars of a trial offer. The booklet will be supplied to anyone interested by the Yarnall-Waring Company, Chestnut Hill, Philadelphia.

The Westinghouse Electric & Manufacturing Co., have issued a miniature catalogue 9-A-2, which deals with industrial heating apparatus. This includes footwarmers for men employed in outside capacities, where they are more or less stationary, such as gatemen, police officers, etc. Water heaters, hot tables, glue pots, etc., all electrically operated are included. Formulae connected with heating of buildings is given a place in the booklet, thus making it of practical use to the engineer.

UTILIZING COAL DUST

The latest contribution to the universal problem of fuel economy is a British invention for efficiently utilizing waste coal, peat, lignite, and other low-grade solid fuels. The material is made into blocks of any desired shape or size, each block being composed of a number of layers. When the mass is burning it tends to separate along the layers, thus exposing a large area for complete combustion and giving a result similar to the burning of raw coal. Licenses have been granted to many British collieries to work up coal dust into this form. The cost of production is stated to be nearly one-third less than that of briquetting in the ordinary way, and the resulting fuel can be sold at only 10s. per ton less than the price of raw coal. The regular form of the blocks facilitates the storing of the fuel on board ship

FUEL ECONOMY TRIALS IN GREAT BRITAIN

Important experiments have recently been made in Great Britain with power alcohol as a fuel for motor propulsion on vehicles. The trials were made with mixtures of alcohol and benzol, and the results were very promising. Certain modifications were made to the engine and its accessory parts to suit the new fuel, and the experiments will be continued with ether as well as alcohol. There is good prospect that British engineers will soon be able to achieve, by an adapted form of engine, very high efficiencies with fuels which can be manufactured in large quantities from cheap and abundant vegetable sources.

BETTER THAN CASTING

The good that comes out of evil is illustrated by the fact that during the recent moulders' strike in Great Britain many engineering firms, unable to obtain castings, were stimulated to develop alterantive methods of producing the parts they required. One large firm, for example, was in urgent need of large pipes, and it set to work to build up pipes of the required shape from steel plates by welding together suitably-formed pieces. Excellent results were obtained, even with complicated shapes, the surface being as smooth as a fine casting. The expense proved to be much about the same as casting, but in the case of special work the labor and material involved in making patterns (which might never be used again) were saved.

HYDRO-ELECTRICS IN GREAT BRITAIN

Owing to the high cost of fuel and the demand for increased production, many British mill-owners are installing water turbines to use moderate heads of water and are using steam plant as an auxiliary. Both plants generate electricity, the hydro plant taking the constant load and the steam plant dealing with additional demands in the busiest hours. The arrangements which several of the leading British electrical firms are making to carry out complete hydro-electrical installations of every size will encourage this movement towards power economy.

THE LATEST AT GREENWICH OBSERVATORY

Once every year a rather quaint ceremony is observed at Greenwich Observatory. An inspection of the Observatory is made by a "Board of Visitors" to whom the Astronomer-Royal presents a report on the work of the preceding twelve months. The latest report shows that although the Observatory was founded centuries ago, at the very dawn of scientific navigation, it keeps in line with the latest developments. A new aerial has been erected to extend the range over which wireless time signals can be received. These signals are now received regularly from the Eiffel Tower, Nauen, and Annapolis. The Observatory also controls the operation of time-balls in different parts of the country. These time balls are hoisted on a prominent mast and released at specific hours by an electric signal from the Observatory. The accuracy of the operation is checked by a return signal from the distant time-ball. Greenwich also controls "Big Ben," the famous clock of the Houses of Parliament.

DEVELOPING HIGH OVERLOAD CAPACITIES

Continued from page 357

affected by the rate of driving is given in Fig. 3. Fig. 4 shows that the boiler starting from a banked fire can take up a 300 per cent. overload in 4 minutes, 23 seconds. From the excellent performance of this boiler at high overloads,—overloads which were limited only by the fusing of the clinker in the low and fair grades of the coal used—it would appear advisable to consider the desirability of using larger grate areas than is customary.

The results further established that the arrangement of baffling which is especially suitable for obtaining maximum capacities does not affect adversely the efficiencies obtained at lower ratings. High overloads could have been readily maintained for indefinite periods if a higher grade fuel had been available.

The combustion results obtained were consistently good. The flue gas temperatures were not extreme considering the capacities developed. The condition of the heating surfaces after tests was found to be good with little accumulations of soot and with no deposits of slag.

The Theory and Practice of Electricity

In These Articles the Theory Will be Developed Sufficiently to Enable the Practical Man to Grasp the Underlying Principles of Apparatus Under His Care, Both Direct Current and Alternating

W. F. SUTHERLAND

EVERYONE is familiar with gravitation and has at least some working knowledge of its effect upon the world in which we live. A somewhat similar force very closely allied to electricity exists in magnetism. The two, electricity and magnetism, are in many cases related as cause and effect and for the proper understanding of dynamo electric machinery an outline of the nature of magnetic force will be given. The mariner's compass is one familiar type of magnetic instrument and in every electric generator and motor magnetism is utilized.

If we take an ordinary horseshoe magnet sold in the stores and place it under a piece of paper and then gently sprinkle fine iron filings on the paper a pattern will be formed much as is shown in Fig. 16. The filings will bunch up around the ends of the magnet and will be thinner the farther away we go from the ends.

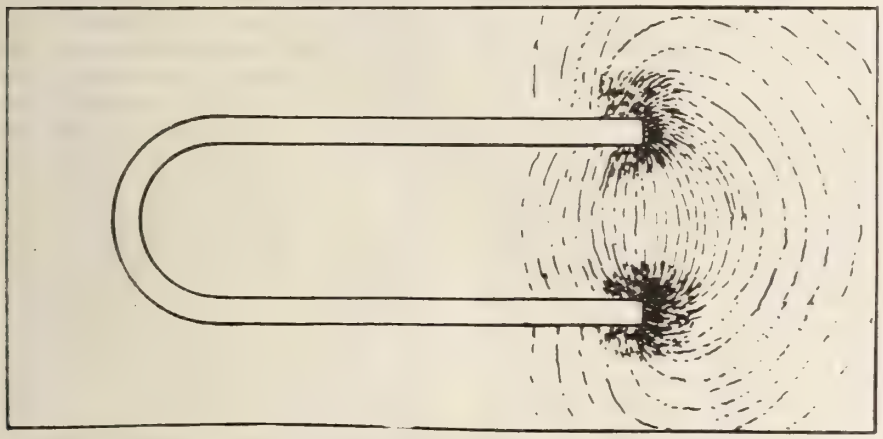

FIG. 16—FIELD OF FORCE AROUND THE POLES OF A HORSESHOE MAGNET AS SHOWN BY IRON FILINGS.

To the ends of a magnet the name of poles is given and it will be seen that the filings arrange themselves in lines from pole to pole much as if something was leaving one pole crossing the intervening space and entering the next. By general agreement the paths traced out by this magnetic force are called lines of magnetic force or lines of force.

A magnet does not have to be U or horseshoe shaped to exhibit the property of magnetism for if we take any hard steel object such as a chisel, a penknife, etc., it can readily be magnetized. If a bar of hard steel is taken and magnetized and iron filings be taken and dusted over paper placed on top of it a pattern similar to Fig. 17 will result. The filings will not bunch completely at the ends but some will be seen to adhere along the sides and will suggest a flow of force out of the bar along its sides as well as at the end. Their concentration will be greater at the poles than at the end suggesting the fact that the magnetic force is greater there. It will also be seen that the lines of force return upon themselves making a complete circuit through the surrounding air and the magnet itself.

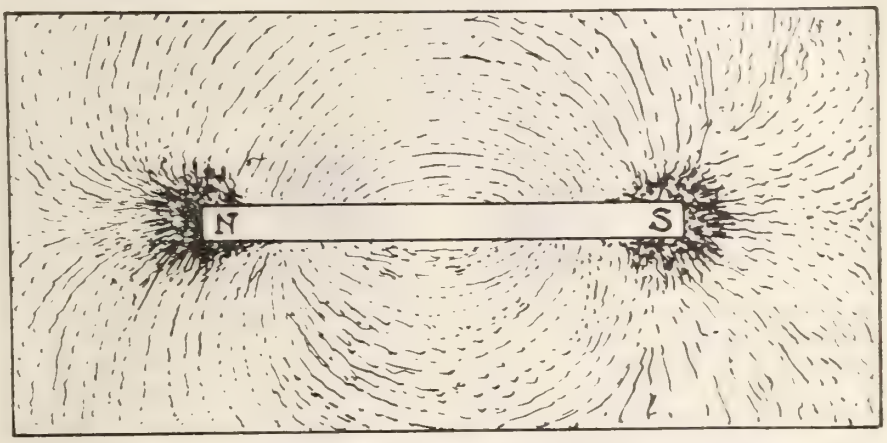

FIG. 17—FIELD OF FORCE AROUND A PERMANENT BAR MAGNET SHOWN BY IRON FILINGS.

Next, if two bar magnets be placed end to end and covered with a sheet of paper a pattern can be made with iron filings similar to either Fig 18 or 19. In one case there will be a suggestion of the lines of force leaving one magnet, jumping across the intervening space and entering the other magnet. While in the other case it would seem as if two fields of force opposed each other and leaving each magnet the lines of force are bent more or less sharply around and return to the other end of their respective magnets.

From the above it may be surmised that the two poles of a magnet are unlike and that they exhibit opposite characteristics. This is true and a further experiment will show that like poles oppose each other and unlike ones attract. The two magnets may be held end to end in the hands and by trying them out it will be found that they will adhere strongly together in one position, while if one of them is reversed they will oppose each other.

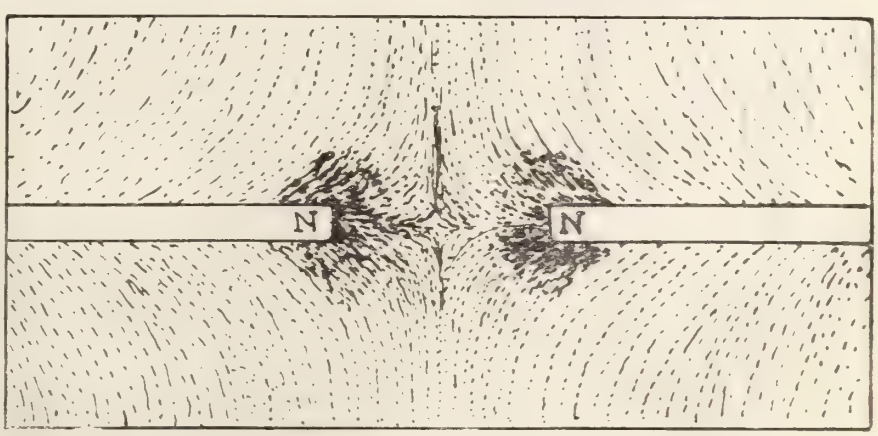

FIG 18—FIELD OF FORCE CAUSED BY TWO BAR MAGNETS WITH LIKE POLES TOGETHER.

The Compass and the Earth as a Magnet

If a bar magnet be tied to a string or other light suspension and be left free to turn about the string as an axis, it will be found to take up a position pointing almost due north and south. If it should be turned end for end and left free again it will turn around and the same pole as before will take up its old position. To this pole, the one pointing north, the name north pole is given, and to its counterpart on the other end, the name of south pole.

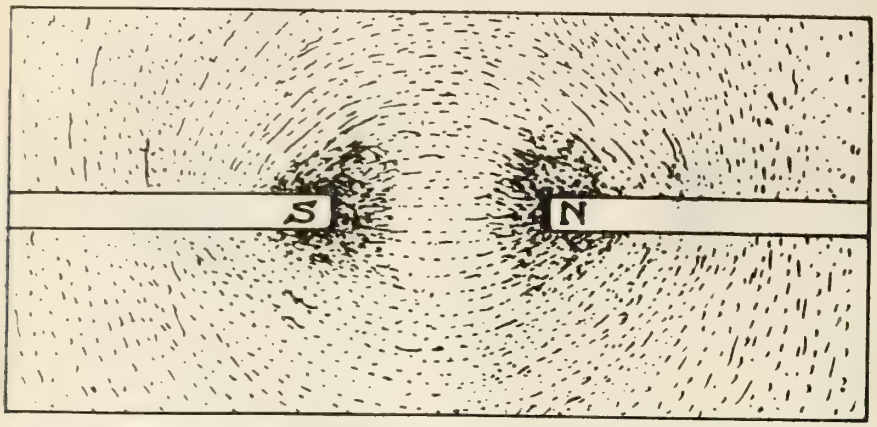

FIG. 19—FIELD OF FORCE CAUSED BY TWO BAR MAGNETS WITH UNLIKE POLES TOGETHER

The compass is merely the scientific adaptation of this fact to the needs of mariners and incidentally it is very old, having been in use by the Chinese for centuries. Fig. 20 will make the action of the compass clear. The earth is nothing more nor less than a huge magnet itself and has two poles, a north magnetic pole and a south magnetic pole. These do not coincide exactly with the geographical ones but lie some distance away.

The lines of force as will be seen from the illustrations are assumed as a matter of convention to leave the south pole of the earth, travel through the intervening space and enter at the north pole. The bar magnet takes up such a position that the lines of force flowing through it and in and out at the ends parallel those of the earth's field and flow in the same direction. This makes the north pole of the magnet the one out of which the lines flow. Note the distinction—while the lines of force are assumed to flow into the north pole of the earth they flow out of the north pole of the earth and that the two are not of the same polarity, but unlike. The difference can always be clearly kept in mind by thinking of the north pole of a magnet as the north-seeking pole.

The lines of magnetic force in the figures shown are merely the stream lines of magnetic flux. A conception of magnetic flux may be secured by using as illustration a simple analogy first given in "Kapp: Dynamos and Transformers."

Suppose we have a tube a few inches long within which is mounted a force pump which, when in operation, will draw in a fluid at one end and expel it from the other. While this small pump is in operation let the tube be immersed in a tub of water all through which are saw-dust particles. After steady conditions have become established, observe the liquid. The whole volume is in motion, within the tube and near its ends the liquid has high velocity, but out in the tub the motion is slow. The saw-dust particles are marking out stream lines in the fluid and the stream lines are continuous in closed paths. The same stream which passes down the tube returns in much wider paths to the other end by way of the whole volume of fluid. The amount of water moving through the tube per second is the same as the amount returning to the other end outside the tube. Here is a picture of the magnetic flux. While this analogy fails at some points, it can be much elaborated and is very useful in picturing the real facts relating to magnetism. There is then a magnetic flux whose stream lines we call lines of magnetic force; this flux pases through the magneto and on around, completing a magnetic circuit. The same total flux is found at every part of a magnetic circuit; the same flux goes all the way around.

The analogy has been used further for impartial explanation of the attractive and repulsive forces between magnets. Suppose we put two tubes with their enclosed force pumps under the water. Each will have its own effect in producing currents. If certain ends are brought together the tubes, by means of these currents, repel each other. If one tube is reversed, by the same means they attract one another and if we name the ends out of which the currents flow north poles, the behavior is exactly the same as for magnets.

Permeability

Not all substances are magnetic; iron, cobalt, nickel and some other metals and alloys are, while the remainder of the elements and compounds are not. Substances are said to be magnetic when they are attracted by a magnet of any kind and this simply means that they are a better conductor for magnetic flux than ordinary materials. Aside from the few exceptions like iron, cobalt, nickel, etc., all other substances have practically the same conductivity and are said to have a permeability of 1. Permeability simply means the conducting power of a material for magnetic flux. Wrought iron and cast machinery steel have about the same permeability; cast iron about half as much. The permeability of soft wrought iron may easily be 1,200 or 1,500.

Permanent Magnets.

Hard cast steel possesses the property of retaining magnetism and the old

FIG. 20—THE EARTH AS A MAGNET.

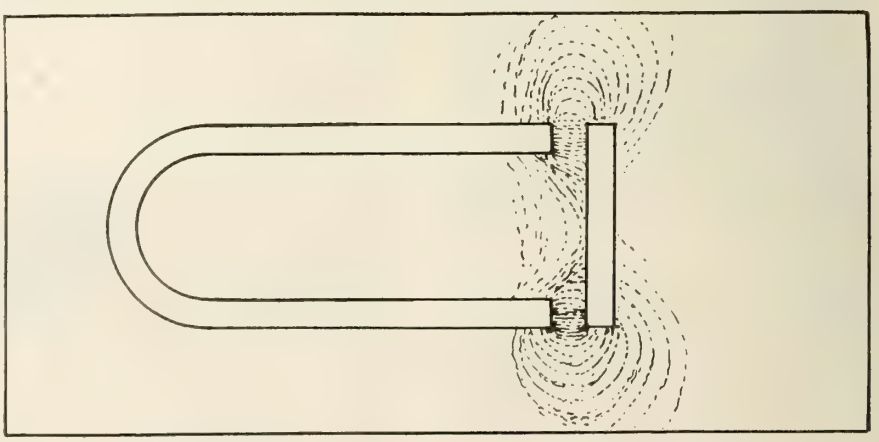

FIG. 21—THE EFFECT OF A KEEPER ON A HORSE SHOE MAGNET.

horseshoe magnet finds considerable use today in magnetos, measuring instruments, etc. It has been advanced by some scientists that each separate molecule of the steel forming the magnet is a magnet in itself and when the bar of steel is magnetized from an outside source these molecules all line up with north to south poles.

They are then supposed to retain this alignment. If the steel be soft they are not capable of retaining it, but return to their former arrangement.

The effect of the varying permeability of various substances on the lines of magnetic force is illustrated in Fig. 21. Here a piece of iron or steel has been brought close to the two poles of a permanent magnet and if by means of a sheet of paper and some iron filings the flux disposition be ascertained it will be found that the major portion of the lines of force forsake the surrounding air and travel through the iron bar or keeper. If the bar be placed tight against the poles it will again be found that nearly all the lines pass through it and very few through the surrounding air.

The next article of the series will deal with the relations between magnetism and electricity.

TRADE ANNOUNCEMENT

The Combustion Engineering Corporation announces the appointment of Mr. Henry Kreisinger formerly of the United States Bureau of Mines, as Engineer of Research.

Mr. Kreisinger was probably the best known man in the Bureau of Mines in connection with such work, having compiled a large proportion of the Government pamphlets on fuel and combustion problems, and his years of experience in Government service will be of incalculable value to the clients of the Combustion Engineering Corporation.

Mr. Kreisinger will conduct investigations for the Combustion Engineering Corporation of a similar nature to those that he conducted for the Government, and the results of his work will not only be available to the clients of that corporation, but will also be supplied to the Government. This branch of the corporation's business is entirely aside from any commercial consideration, and its activities governed by precisely the same fundamental principles that underlie the operation of the Bureau of Mines. The only difference is that Mr. Kreisinger will have a broader field for his studies because of his being able to apply then to practical situations, and further, there will be less financial limitation.

A recent issue of "Coal Age" contained the following story of Mr. Kreisinger's work:

"Mr. Kreisinger was born in the town of Radnice, in what is now known as Czechoslovakia, but at the time of his birth the town constituted a part of Bohemia. He came to America in 1891 at the age of fifteen. In 1900 he entered the University of Illinois, and four years later received the degree of Bachelor of Science. Continuing his studies, he graduated as Mechanical Engineer in 1906.

"After gaining the latter degree he entered the Technological Branch of the U.S. Geological Survey, which had quarters in the St. Louis Exposition grounds. Here he was assigned to the fuel-testing plant, in 1910, when the Bureau of Mines was created, and took over the work of the fuel-testing department of the Survey. Mr. Kreisinger severed direct connection with the Government and became fuel engineer for the Clinchfield Fuel Co., of Spartanburg, S.C.

"While with the Clinchfield Fuel Co., Mr. Kreisinger was frequently consulted on combustion problems by the Bureau. The acquaintance formed and opportunities offered by the Bureau of Mines for research work were so attractive to him, however, that in 1913 he returned as head of the fuel department of the Pittsburgh station. When the Bureau Home in Pittsburgh was changed from the old Arsenal buildings on Butler Street to the new million dollar buildings in the Oakland district, Mr. Kreisinger was given increased opportunities for the research work of which he is so fond. As a designer of fuel-testing apparatus he has perhaps no peer. The result has been that the fuel-testing laboratories of the Pittsburgh station are the most complete of their kind to be found anywhere."

While connected with the Combustion Engineering Corporation as research engineer, Mr. Kreisinger will make his headquarters at the Bureau of Mines station in Pittsburgh. By this arrangement a closer co-operation between the two institutions will be maintained. The first problem upon which Mr. Kreisinger will centre his efforts will be a thorough testing of the powdered coal plant of the Bureau of Mines at Milwaukee, Wis.

While engaged in this work he will have under his direction four men from the Bureau of Mines fuel-testing laboratories and fifteen others who will be carried on the pay-roll of the corporation. These men will be chosen from newly-graduated engineers and men who will be seniors in college next year. He will be allowed the full and unrestricted use of any equipment or apparatus owned by the Bureau.

Mr. Kreisinger is a member of the Sigma XI engineering fraternity, the Coal Mining Institute of America, the American Society of Mechanical Engineers, and the American Society for the Advancement of Science.

The Canadian Engineering Standards Association have informed us that a stock of the most important publications of the British Engineering Standards Association are now available for distribution. Of ccurse a nominal price must be charged for these publications. Below is a description of some of these books.

Requests for copies should be addressed: Secretary Canadian Standards Association, Room 112 West Block, Ottawa, Ont.

10-1904. British Standard Tables of Pipe Flanges.—This report gives the British standard dimensions for pipe flanges for steam and water piping for low pressures and high pressures, dimensions of welded-on flanges for pipe lines, for working steam pressures of 125, 225, and 325 lbs. per square inch, dimensions for short flanged bends and tees of cast metal for pressures up to 325 lbs. per square inch, and dimensions for long bends of wrought iron and steel. 25 cents net.

46-1909. British Standard Specifications for Keys and Keyways.—The specification covers material, tests, definitions and tables of dimensions for three classes of key: (a) Parallel Sunk Key; (b) Taper Key; (c) Taper Sunk Key. 25 cents net.

21-1090. Report on British Standard Pipe Threads for Iron or Steel Pipes and Tubes. (Revised November, 1909).—This report gives definitions and tables of dimensions for British standard pipe threads. In this system the Whitworth form of thread is employed, but fine pitches are used, and both parallel and conical screw ends are provided for. 25 cents net.

95-1919. British Standard Tables for Use in Engineering Workshops, Giving Corrections to Effective Diameter Required to Compensate Pitch and Angle Errors in Screw Threads of Whitworth Form.—This important paper gives the necessary information in convenient form for correcting threads of Whitworth form from 28 per inch to 2½ per inch. 25 cents net.

BOOK REVIEWS

The McGraw Hill Book Company Inc. 239 West 39th Street, New York, have just issued four new publications bearing on practical electricity. These books cover a very wide field, and will be found of great assistance to those interested in the different lines. The books are by well-known authors, and provide a welcome addition to the literature of the electrical science. They are "Armature Winding and Motor Repair," by Braymer, which has been very well received, the first edition being sold out in less than one month. The second is a new and revised edition of Croft's Wiring for Light and Power. It contains all the rules for wiring contained in the National Code of U.S. "Direct Current Motor and Generator Troubles," by Gandy and Schacht, tells all about tracing, preventing and remedying the troubles that the direct current machine is heir to. The last one is Lauer and Brown's "Radio Engineering Principles," which is an authoritative work on the developments in radio made during the war. It is supported by the signed recommendation of the Chief Signal Officer of the U.S. army, Major-General Squier. These four volumes cover a very wide field, and should be welcomed by the electrical profession in general.

Editorial Versatility

IT IS hard to realize just how much wealth and days of work are shot to pieces during the course of a strike. an editor. The query is, "To settle a dispute, would you be so kind as to allow me to ask in your 'Knotty Points' column why the funnels on almost all steamers are painted with colors red, white, and black? Thanking you in advance, I remain, yours truly, Reader."

To which the busy editor replies: "The colors are most conspicuous."

While not disputing the fact that such a combination of colors is conspicuous, it would seem to us that the editor's lack of knowledge of the real reason was only equalled by his willingness to oblige the reader. This is, as every seafaring or shipping man knows, to identify the company the steamer belongs to. In the old days of the sailing ship, every line had their own house flag, and the hulls of the ships were painted with a particular color scheme. For instance, one large English sailing ship company made a rule of painting their ships white, from truck to water line, blocks, yards, masts and every fixture conforming to this color. They were known as the white ships. An Italian line of sailing ships was known by its fluted masts, the masts themselves being white, with the flutes picked out in light blue. Another line would have a white hull, with painted ports. With the introduction of the steamer, the funnel lent itself to distinguishing marks, and these were made as near as possible the same colors as the house flag, though of course this was not always the case.

For instance, the red funnel and black top, in conjunction with a square red flag carrying a golden lion and globe, is the symbol of the Cunard Line, while a cream-colored funnel with black top and a red swallow-tail flag with a white star on it signifies the White Star Line. The Allan Line and the Dominion Line both used a red funnel with a black top and a white band, the distinction being in the position of the band. In one case it was close up against the black, while in the other there was a band of red between the white and the black. Every line of any note has its own particular marks.

The reason the Hamilton reader concluded that red, white and black was the favorite color of the seas, is probably because a red funnel, with a white band and black top is the distinguishing mark of the Canada Steamship Lines, and in the thriving ocean port of Hamilton these are probably the most frequent visitors. We imagine our editorial friend, from his familiarity with nautical matters, must have just returned from reporting the America Cup races. While on the subject of funnels, we would like to ask him if a ship with two funnels goes faster than a vessel with one, or vice versa?

Our $4,000 Legislators

DURING the debate on the Government's proposals to finance the building of foreign ships in Canadian yards by the endorsement of the purchaser's notes, some airy persiflage was introduced by our high-priced legislators. Mr. Duff, one of the members from the Maritime Provinces, was opposing the proposals, and Mr. Morphy asked him if the inclusion of the wooden shipbuilding yards would cause him to look more favorably upon them. Mr. Duff answered that the Government should not pick out any particular industry for their favors. Mr. Morphy again put the direct question that if the Government had included the wooden shipbuilders, would Mr. Duff have given the Government his support? Mr. Lalor chimed in with, "Come on, that's the second time." To this Mr. Duff answered in cryptical fashion, "Pork and beans make a very good meal if there are no stones in them, as the honorable member should know." Here the Deputy Speaker asked the members to assist the Speaker to preserve the dignity of the house. Mr. Duff thereupon asserted that the shipbuilders of Nova Scotia had not asked for assistance, and believed in standing on their own feet. Mr. Morphy asked if the wooden shipbuilders would refuse assistance if offered them. Mr. Lalor again interjected "Come across." Mr. Duff again answered by his former allusion to pork and beans, and Mr. Lalor came back, "You have enough wind. You do not need any beans."

Such is the high level at which the debates are kept by our parliamentary representatives. However, probably $4,000 a session is not so very much to pay them for exhibiting such a pretty talent in patter. Look at the money Charlie Chaplin makes, and he is not so very much funnier, and probably not as vulgar.

What Strikes Cost

IT is hard to realize just how much wealth and days of work are shot to pieces during the course of a strike. We have come to look upon strikes as part and parcel of our industrial life, while it is time that we started to regard many of the strikers as thieves and robbers that go about putting their hands in the pockets of the workers, taking out many times what they ever replace. For instance, strikes in Pennsylvania during 1916-17-18-19 meant 10,179,243 days' work lost, and wages lost amounting to $28,664,871. These figures do not take in coal or steel strikes.

Report on the New England Coal Situation

DEPENDING, as we do in Canada, to such a large extent on the United States for our coal supply, the situation in the Eastern States has a personal interest to us. A report has just been made covering the first quarter of the year, from April 1, 1920, to July 1, 1920, showing the distribution of coal from the Southern fields. This is addressed to the Governors of the six New England States, and is signed by the Lieutenant-Governors and State Fuel Administrators of the same States

The first paragraph states emphatically that unless granted quick and effective relief the New England States will be facing the worst coal crisis in their history, and that it will be "much worse and more dangerous than during the war."

The requirements of New England for the twelve months are set down, conservatively, at 25,000,000 tons, this assumes a winter of just ordinary severity. At the end of 1918 there was a reserve of about 1,000,000 tons, while figures for 1919 are not to hand, there having been no fuel administrator at this time. The movement of coal for the first quarter of this year means that if there is no improvement there will be a shortage of 6,500,000 tons. This means that after hospitals and public utilities are provided for, New England factories will have to go on half time or less. A point which the report does not mention is the suffering to the employees of these factories by having their earnings cut in half at the time of year when living conditions are most onerous. The report states that the whole problem is one of transportation only. It claims that there is plenty of coal and plenty of miners to supply all normal needs of the Eastern States, but that the coal they should be receiving is being shipped for export at fancy prices. The salt water piers at Hampton Roads, from which the New England States draw the greater portion of their surplus, have been working to capacity, but have been shipping all their supply to foreign customers, to the detriment of those at home. New England cannot get this coal because the foreign buyers are out to get the coal no matter what the price that is asked.

In order to get some measure of relief, the representatives of the suffering states have asked the Interstate Commerce Commission to divert a portion of this export coal to them. They point out that this would not injure any other part of the country. No more coal or cars would be used than used at present, if the New England consumers were granted half a million tons a month out of the coal now being shipped through Hampton Roads.

Being unable to get coal from the Southern fields, these buyers turn to the Pennsylvania fields. This is the field that we in Canada draw large quantities of coal from, and conditions there interest us. The report points out that the influx of all these new buyers to the Pennsylvania market results in one bidding against the other, and contracting for more coal than the field can supply. The operators then give coal to these new buyers at high prices, and neglect their old customers. These in turn get alarmed, and try to secure coal to cover their requirements and soon, in the words of the report, "everybody is trying to buy two tons to get one."

All this is bad enough, but the report claims that the coal owners operating through the Coal Operators' Association, which is a powerful organization having large offices in Washington, are deliberately issuing propaganda to mislead the people in the States as to the true situation. The abnormal profits to be made out of exporting coal will not be lightly relinquished by these coal operators. Further, they take the view that as long as profiteering is conducted at the expense of the foreign buyer, the U.S. Attorney-General will not bother them. The authors of the report state that it has more than once come to their knowledge that operators had refused to sell coal at their own price when they found it was for an American port. In the light of this statement, the hopeful outlook of a Toronto paper that the United States would not let Canada go short seems optimistic, indeed.

In the report the attitude of the British Government, which firmly restrains all coal export till the home market is provided for, is noted. They point out that much as Great Britain needs the export business to restore the balance of trade, they show no intention of starving the home market in order to serve export. In the meantime, the United States operators are making hay while the sun shines. The result of all this is that recently a cargo of coal in Boston Harbor sold for $22.30 a ton. This is $8 a ton higher than the highest price in 1917, the year the States went into the war. Before the war, Virginia coal sold afloat in Boston at an average price of $4.50 per ton. The railroad reserves in the New England States are fast dwindling away, and the probabilities all point to a general breakdown in transportation facilities during the winter.

This is by no means a cheerful outlook, and it is an outlook in which Canada has a vital interest. We know that there was a serious shortage here just a few weeks ago. It is doubtful if there is any great reserve in Canadian factories, at least in Eastern Canadian factories. This is a time for economy and preparation for the winter that will too soon be with us. Every man who is in charge of a steam plant, or who has anything to do with the burning of coal, should look carefully into his daily operations and stop all waste. We could get along very well on little more than half the coal we use if it were used efficiently. The money that would be saved could be put into extensions of factories and to the development of our own coal resources. As long as we depend on importation for our fuel supplies, so long will we be at the mercy of just such situations as the present. It is not a comfortable position to be in.

BROWNED ALUMINUM

To protect aluminum and aluminum alloys from corrosion, L. von Grotthuss has tried the experiment of browning the metal electrolytically. The aluminum is suspended in an electrolyte consisting of a sulphur compound of molybdenum and zinc is used for the anode. The cell is maintained at a temperature of 60 deg. to 65 deg. C. The aluminum is soon covered with a dark brown coating. The metal may be bent or rolled without cracking the coating. A piece of aluminum thus coated was immersed in a salt solution for two months without showing the slightest traces of corrosion.—Abstracted from Metal and Iron.

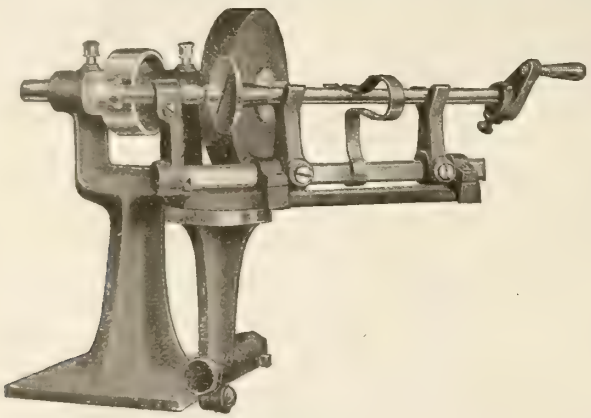
An automatic wireless call device was recently described by Major Basil Binyon before the Wireless Society of London. By means of an aerial which had been erected, Major Binyon was able to give a practical working demonstration of this novel piece of mechanism. Pre-arranged messages were received from the wireless station at Slough, and the selector mechanism proved beyond doubt that it would respond only to signals for which it was set to receive. By the use of this apparatus it is only necessary to employ one operator on board ship, since during the less busy hours of the day the automatic call device may be left to take incoming signals. On the receipt of a message giving the call signal of the ship in which it is installed, or the distress signal S.O.S., a relay is put in action, a bell rung, and the operator called to his instruments.

Progress in New Equipment

GRINDER FOR VALVE FACING

D. F. Dunham, 830 West 37th Street, Los Angeles, Cal., supplies us with the following information of his valve grinder which he has placed on the market:

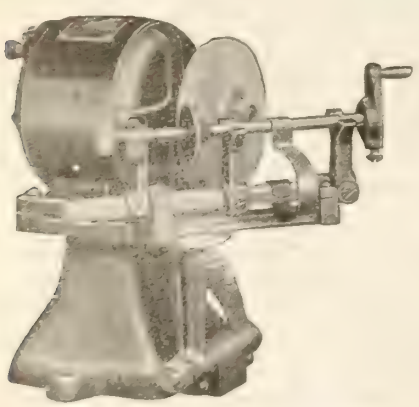
The machine, as illustrated, is arranged to face valves of any size and angle, and if the valve centre has been mutilated it makes no difference, as an adjusting screw with a ball and socket joint overcomes this defect. The valves are ground true with the stem and not with the centre.



ILLUSTRATING THE BELT TYPE MACHINE.

A spring stop can also be arranged for grinding valve seat reamers.

The valve is worked back and forth on the face of the wheel, the valve being revolved meanwhile. The arm on the machine is graduated from 30 to 60 degrees, and the strong, rigid construction can be clearly noted. Three models are made Nos. 1 to 3, the first a motor grinder, the second a belt-driven grinder, and the third a grinding attachment, as shown.



THE MOTOR DRIVEN MACHINE.

DIRECT-CURRENT SERIES-WOUND MOTORS

For severe intermittent varying speed service where heavy starting torque is required, such as for cranes and hoists, the Westinghouse Electric & Manufacturing Company has recently brought out the type "HK" direct-current, series-wound motors. These motors are especially designed for use where the load consists of a series of starts, stops and reversals, the motor being idle for only short periods of time.

These motors are of enclosed construction with small openings in the lower part for ventilation. Covered openings in the top half of the frame give access to the brushes and the commutator. The most prominent feature of this motor is its compact construction, giving small overall dimensions, light weight and great mechanical strength.

The motor has a forged open-hearth steel frame and solid forged-steel feet. The motors above three h.p. rating are equipped with commutating poles so that high momentary loads can be carried without series sparking, and long life of commutator and brushes thereby insured. All field coils are thoroughly insulated and impregnated. The brackets are strong and rigid, each complete with oil well and bearing housing. Oil ring lubrication is used. The brush holders are clamped to insulated rods mounted on the front bracket which are dowelled in place. The position of the brushes is thereby fixed for both directions of rotation.

Armature coils are form-wound and thoroughly insulated and impregnated before being placed in the slots. A blower is placed in the rotor which effectively ventilates both armature and field windings. This allows a smaller diameter armature to be used, resulting in low flywheel effect, consequently little energy is required to start and stop the motor, thereby reducing to a minimum, wear and tear on bearings and brakes.

Electrically-operated shoe-type brakes are supplied when ordered. They are bolted to the machined lugs on the motor bracket, making a compact unit of motor and brake. The brake is simple and rugged, and provision is made for adjusting for wear of parts.

The company states that the ability of any motor to do its daily work, as far as its temperature rise is concerned, is determined by the continuous rating it will carry at a safe temperature. A ventilated motor has a larger continuous rating than a non-ventilated motor of the same short time rating. A ventilated motor rated 7½ h.p., one-quarter hour, has about 30 per cent. more continuous capacity than the non-ventilated motor rated 7½ h.p. one-half hour.

GENERAL VIEW OF MOTOR.

The freezing of some water which had leaked into a cast-iron column carrying a footpath produced an unexpected effect in Philadelphia. The column, according to the Engineering News Record, was open at the bottom, but fitted so well on its base that it gradually filled with water through leakage at the top. The water froze during the winter, and in expanding squeezed out at the bottom of the column, which was lifted, together with the pavement, about 8 in. The column was 16 ft. high, and was not damaged. The ice was melted out, and after the column was settled down again it was made water-tight at the top.

The Operators' Point of View

RUPTURED TUBE IN WATER-TUBE BOILER

Regarding Mr. Wright's ruptured tube, my guess is that the water came over from the other boilers in the battery as the result of the rupture stopping the delivery of steam from the crippled boiler. This guess is on the assumption that the crippled boiler was not the only one delivering steam into the header.

It is pretty well known that with high water the sudden opening of the safety valve will cause a rise in the water level and at a point below the valve outlet there will be a piling up of the water to such an extent that the valve will discharge water. If the boilers were equipped with non-return valves as they ought to be the lowering of the pressure in the crippled boiler would have caused the non-return valve to close and thus reduce the tendency of the other valves to prime.

The shape of the rupture indicates that the metal was soft at the time of rupture. This is a condition which is very apt to occur in tubes inclined at such an angle as are those in Mr. Wright's boiler if the rate of evaporation is high, due to the reduced heat-absorbing quality of the mixture of steam and water with which the tubes are filled and the higher the rate of evaporation the more steam and less water there will be.

This risk is increased if the headers are of the sinuous type instead of the box type.

R. McL.

BOILING POINT OF AMMONIA

Editor Power House:

Dear Sir,—A little more detail than shown in your note on "The Boiling Point of Ammonia," on page 44 of July 5th issue of Power House may be of interest.

"The boiling point of a liquid is the temperature at which, under application of heat, the liquid changes into vapor without further increase in temperature, the pressure remaining constant. It also presupposes that the vapor is of the same substance as the liquid from which it rises. Water commences to boil at approximately 212 deg. Fahr. at atmospheric pressure, forming steam, or water vapor, and will continue to boil at that temperature as long as any water is left. But with the aqua ammonia a different condition exists. Aqua ammonia is merely a solution of ammonia gas in water. If heated, the temperature starts to go up, and very shortly the solution commences to give off bubbles of ammonia gas, depending in quantity on the strength of the aqua. The bubbling increases and the temperature continues to rise, and does not become stationary until the boiling point of water is reached, when the solution no longer contains any ammonia, but is only water. Different strengths of aqua ammonia will commence to give off gas bubbles at different corresponding temperatures, but these can hardly be called the boiling point of aqua ammonia.

Anhydrous ammonia, on the contrary, will have a definite boiling point for a given pressure, since the condition merely exists between the liquid and vapor forms of ammonia itself. Its action is precisely that of water, though at a different temperature, this being 28.5 deg. Fahr. below zero at atmospheric pressure and about zero at 15 pounds gauge pressure. In fact the analogy between ammonia and water is quite strong in several ways. Ammonia can be frozen, melted, and vaporized just as water can, and in liquid form will dissolve many substances that water does, again depositing them upon evaporation."

"W. C. KLOTZ."

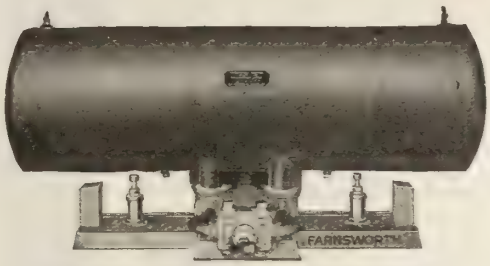
MONTREAL TORONTO WINNIPEG

A Real Canadian Boiler Feeder

THE BEST IN THE WORLD

Ask the Canadian Farnsworth Company about these machines for your steam plant. We build boiler feeders from 20 to 1,000 H.P. each.

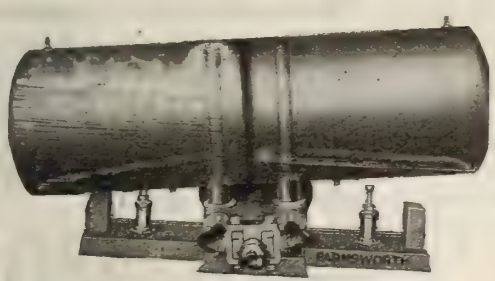


The Farnsworth "Duplex"

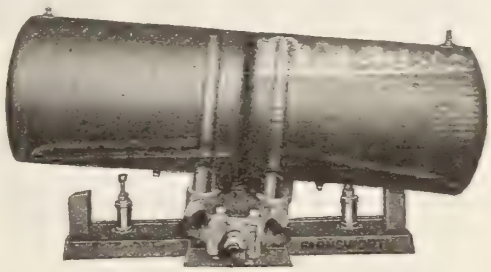
Our Engineers will give you expert advice on boiler feeding and condensation problems. No plant too large.

This Machine is the Product of Canadian Brains and Skill—Made in Canada by Canadian Engineers—the Last Word in Efficiency.

Study the Construction of this Machine.
Have you ever seen a Simpler Machine for the Purpose?
Everything designed for simplicity.
Least moving parts of any boiler feeder on the market.



No springs—No levers—No weights—No check valves to give trouble. Nothing to adjust. No necessity for adjustment. No trumnions, or bearings to bind and stop the action, or leak, and mess up your boiler room.



No open vents to waste your steam—A mechanically perfect Duplex steam valve—Can't leak and can't stick—No renewing of faulty discs.

Study the action of this machine—You have seen the common Return Trap in action—You have seen it "Hold up" the return lines—You have heard it "Pounding" and seen it blow steam through the open vent.

An open vent will waste at 50 lb. pressure about 15 H.P. per hour of your steam—Surely an expensive proposition.

Our Duplex boiler feeder or pump can't waste steam—It's a complete closed loop system, impossible with the common return trap.

Gives a continuous flow to boilers—Continuous drainage from heating apparatus—Continuous equalization between boiler and apparatus.

BEACH 825

NEW MOTOR FUEL NOW USED IN NATAL

Report to Admiralty Says it Has Been Found Possible to Produce It in Large Quantities

London, July 1.—After a series of trials in motor boats, the British Admiralty has just made a confidential report on the far-reaching possibility of using a new motor fuel—"Natalie"—in naval vessels.

This substitute for gasoline which has been used successfully three years in Natal, South Africa, the fuel manager of an automobile association said to-day, is a mixture of alcohol and ether and other things, and is made cheaply in South Africa, where there are large tracts of waste vegetation, from which power alcohol can be extracted.

It is manufactured in some places as a by-product of the sugar industry.

PLATE-WAYS FOR MOTOR TRAFFIC

At the recent annual meeting of the British Science Guild Lord Montagu of Beaulieu made an interesting suggestion regarding new roads for fast motor traffic. He proposed that "plate-ways," consisting of iron plates or concrete two feet wide should be laid down to form an efficient bearing surface for the wheels of motor vehicles. Properly constructed, such plate-ways would halve the tractive effect required to propel a vehicle, as compared with what is necessary on a first-class macadam road. He reckons that the cost of construction would be half that of a single line of railway and that the expense of operation would be very much lower.

The manufacturers of concrete pipes by the "Hume" centrifugal process—Hume Pipe Company, South Africa, Limited—is described in a paper by Mr. W. Wolstenholme recently read before the South African Institution of Engineers. The materials employed with the cement are crushed stone from the mines in the Witwatersand area, and, for reinforcement, discarded winding ropes, of which large quantities are available. The ropes which are slowly rotated, are cut into suitable lengths, annealed, and unstranded, and then woven into cages which are placed in the pipe moulds first. The concrete is thrown into the moulds until the required amount is furnished, the machine is gradually speeded up, and the centrifugal force causes the material to be evenly distributed throughout the length of the moulds; water is also driven out by this method. Six 4-in. or 6-in. diameter pipes can be completed in eight or nine minutes, and four 15-in. or 18-in. pipes in fifteen minutes. Larger sizes up to 60 in. diameter can be finished in about twenty minutes. Sizes up to 9 in. diameter will withstand a working pressure of from 300 to 350 lb. per square inch, while larger sizes have been tested up to 210 lb. per square inch. When subjected to excessive pressure these pipes become a mass of pores, and have cracks which allow the pressure to escape. The pipes do not, therefore, fail in the manner of a cast iron pipe.

A NEW FILLING METAL

There are frequent calls for a filling material to repair cracks and small holes in very light castings, which cannot well be welded. Various methods have been used for this purpose, but the latest is in the nature of a metal having a very low fusion point, and a comparatively high tensile strength. The new metal is known by the name "Metaloid." The composition of the metal is a trade secret, but in appearance it is about the color of solder, but is remarkably light in weight, being of less specific gravity than aluminum. In making a repair, the casting is heated to a temperature of 200 degrees Fahrenheit, and the bar of "Metaloid" is rubbed over the part to be repaired. It adheres closely to the casting, and makes a strong and satisfactory repair. The "Metaloid" requires no heating, and it also provides a guide to the correct temperature of the casting. If the latter is too hot, the "Metaloid" will give off a blue flame when applied to it. If too cold, the "Metaloid" will not run at all, while at the correct temperature it flows quite readily with no sign of burning. Holes in castings have been filled, and the casting afterwards subjected to 300 lbs. per square inch water pressure, the Metaloid showing no signs of leakage. The new metal has been largly used in the repairing of crank cases and radiators of automobiles, and should be of great use in the general engineering field. At the present time it is being tested out by the engineering department of a large Canadian sulphite mill with a view to determine its acid resisting qualities.

"Metaloid" is handled in Canada by Messrs. Kennedy & Kennedy, Tyrell Building, King Street E., Toronto.

PERSONALS

T. E. M. Murphy, who for many years has been in business for himself, is now associated with the Gates Engineering Company, Limited, 348 St. James St., Montreal.

John W. Gates, formerly president and general manager of the Gates Refractories, Limited, has resigned his position with this firm and has opened an office at 348 St. James St., Montreal, where h will carry on business under the name of the Gates Engineering Company, Limited. The new organization will be under the direct supervision of Mr. Gates, and will specialize in boiler settings, special furnace brick work, and general contracting for power plant furnace installations. Mr. Gates has had a life-long experience in this line of work and is the patentee of the Gates boiler furnace blocks. He has supervised some of the largest boiler setting installations in Canada.

Requires Very Little Attention

Do you want efficient and reliable steam trap service without having to give the trap constant attention? Then adopt

The Long Patent Steam Trap

Has important features which CLAIM your attention. Absolutely guaranteed. The Long trap is automatic and requires no valves except those which control the admission of steam to the apparatus to which the trap is attached.

The trap is regulated to work against any pressure between 1 and 200 pounds. Being open at starting, it cannot become air bound this doing away with air cocks or vents—Does Not Freeze.

It is capable of draining from 900 to 1,500 feet of one-inch pipe.

The Long Trap may be applied to drain steam mains jacket kettles and separators, and can also be used in drying room systems.

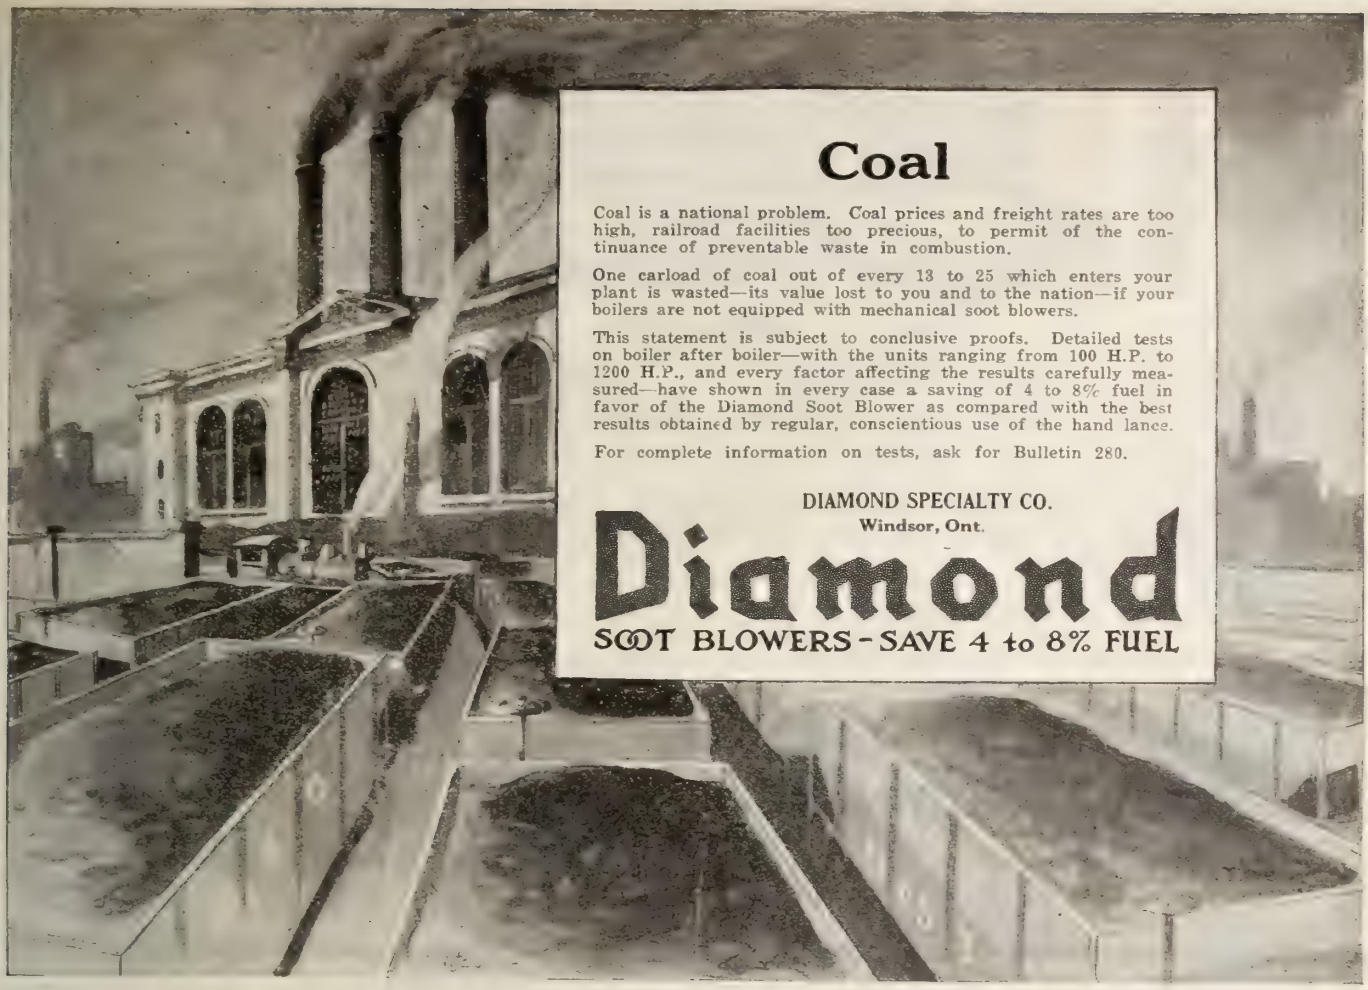
NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,
New York, U.S.A.



Coal

Coal is a national problem. Coal prices and freight rates are too high, railroad facilities too precious, to permit of the continuance of preventable waste in combustion.

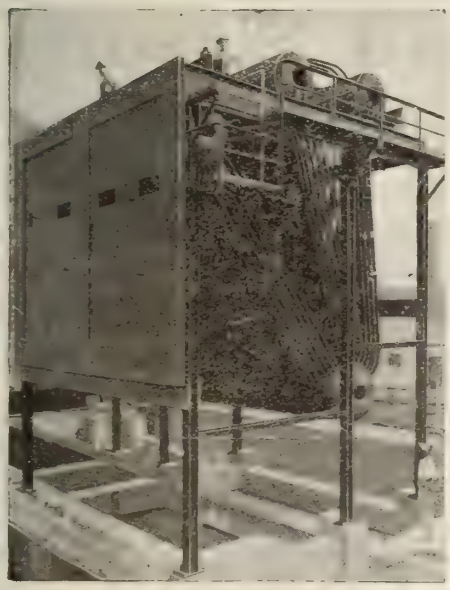
One carload of coal out of every 13 to 25 which enters your plant is wasted—its value lost to you and to the nation—if your boilers are not equipped with mechanical soot blowers.

This statement is subject to conclusive proofs. Detailed tests on boiler after boiler—with the units ranging from 100 H.P. to 1200 H.P., and every factor affecting the results carefully measured—have shown in every case a saving of 4 to 8% fuel in favor of the Diamond Soot Blower as compared with the best results obtained by regular, conscientious use of the hand lance.

For complete information on tests, ask for Bulletin 280.

DIAMOND SPECIALTY CO.
Windsor, Ont.

Diamond
SOOT BLOWERS - SAVE 4 to 8% FUEL



Connelly Water Tube Boilers (Fatented U.S. & Canada)

are of the 4-drum type; have 100% tube area in the path of circulation, and deliver steam superheated to from 5 degrees to 10 degrees Fahrenheit. Simple in design, no flat surfaces, no stay bolts, no crown bars, no braces, no handholes, free from joints.

All parts easily accessible for cleaning, both internally and externally. Can be built in units from 200 H.P. up to 4,000 H.P. and 300 lbs. pressure. 150,000 H.P. in successful operation.

REGISTERED COPPUS U.S. PAT. OFFICE

In Glass Works

In the Glass Division Power Plant of the National Lamp Works out in Cleveland, Ohio, they burn gas coal screenings and producer tar — difficult fuel to burn economically. Yet with the 4-18" COPPUS Tubo Blowers which they operate, full steam pressure is maintained in their 4-250 H.P. Stirling Boilers—and cheap fuel is efficiently burned. Without these Blowers, one of which is shown above, additional boilers would have been necessary last fall. With their aid, however, the heavy plant load is easily handled.

Before the National Lamp Works installed COPPUS Blowers a careful investigation satisfied them that for efficient operation, low steam consumption, and sturdy dependability, COPPUS Blowers stand in a class by themselves. And after practical proof that COPPUS Blowers are all that is claimed for them, Mr. Bretz, Plant Superintendent, expresses himself as "highly pleased with them" In the National Lamp Works, as in thousands of plants in every industry, COPPUS Blowers have proved profitable investments.

Why not find out exactly how and why "COPPUS EQUIPMENT CAN SAVE YOU MONEY." Write us and our engineers will help you solve your combustion problems. If you haven't a copy of Blower Catalog write for one to-day.

KERR
("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

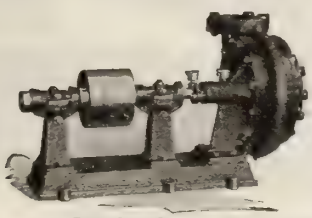
Kerr Engine Co., Ltd., Valve Specialists **Walkerville, Ont.**

AMERICAN-MARSH PUMPS

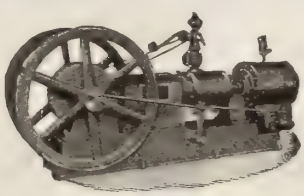
SIMPLE RELIABLE EFFICIENT

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—

Power Pumps
Deep Well Engines
Air Compressors
Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

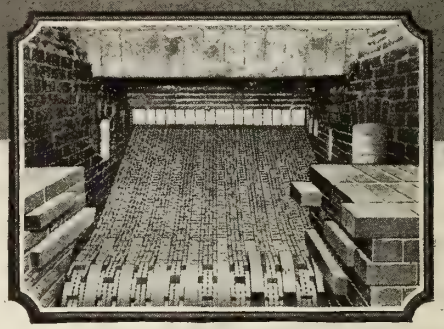
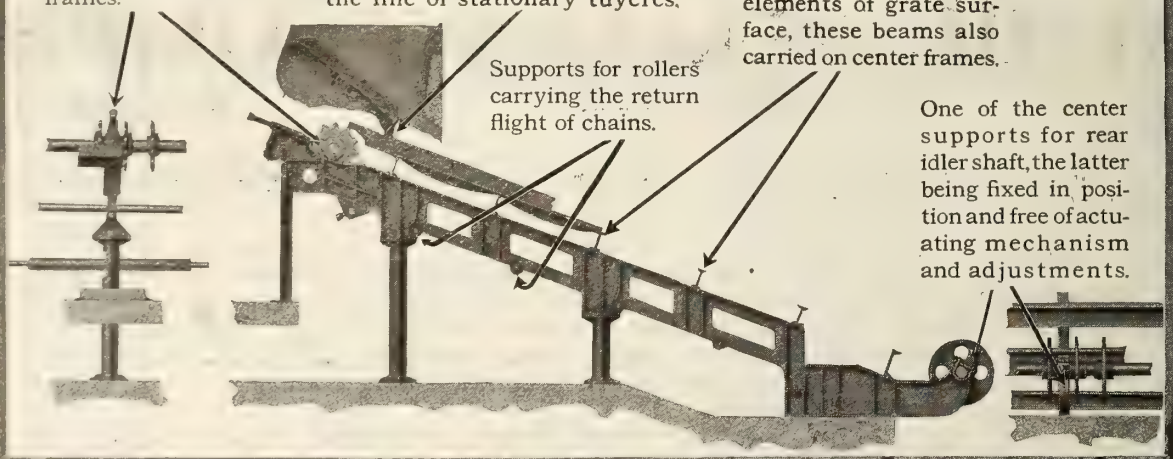
THE STOWE STOKER

EMPLOYING MECHANICAL DRAFT

Its fundamental principle is a conveyor feed, positive in action from coal-hopper to ash-pit



Detail of Center Frame



Adjustable sprocket shaft box carried on center supporting frames.
Hopper plate support for wide stokers, carried by center frame through the dead plate that starts the line of stationary tuyeres.
Supports for rollers carrying the return flight of chains.
I-beams supporting all elements of grate surface, these beams also carried on center frames.
One of the center supports for rear idler shaft, the latter being fixed in position and free of actuating mechanism and adjustments.

LACLEDE

A BUSINESS INSTITUTION

A Single Stoker for Units up to 1500 H. P.

Think of being able to supply your 1500 H. P. Boiler with a forced-draft, conveyor-feed stoker in *one* large unit!

It means doing away entirely with the high maintenance of a center wall, which fills up furnace space and necessitates two stokers to a boiler.

THE STOWE STOKER is built in *single units* for boilers up to 1500 H. P. rated capacity, producing an actual capacity of 300% rating.

This is possible because of the simple, common-sense method of supplying air to the Stowe Stoker, and because of the efficient use of *center supporting frames.*

The illustration across the page shows the detail of one of these sturdy center frames. Three of them are used on a Stowe Stoker 20' 9" wide, making in all five supports for all cross members such as idler shaft, sprocket shaft, hopper plates, tuyere supports, and lower rollers.

Note that the center frame is carried down to the foundation. This is the last word in massive, durable construction, and contributes much to the success of the *forced-draft, conveyor-feed* Stowe Stoker.

We also manufacture the L-C Chain Grate Stoker—the Natural-Draft Type for Higher Volatile Coals—Dominant in this Field Today.

SURE, YOU KNOW

Dependable Furnace Linings insure dependable boiler furnace operation. You know that the more joints there are in your settings the more chance there is for destructive influences to act upon them. You know how quickly ordinary fire brick linings "come down." As surely as you know these facts you should know the facts about

BETSON'S
REG. U.S. TRADE MARK PAT. OFF.
PLASTIC FIRE BRICK

that forms a seamless one-piece setting of high refractory materials of great tensile strength, and in which expansion and contraction have been neutralized. This one-piece construction assures a permanent boiler furnace lining.

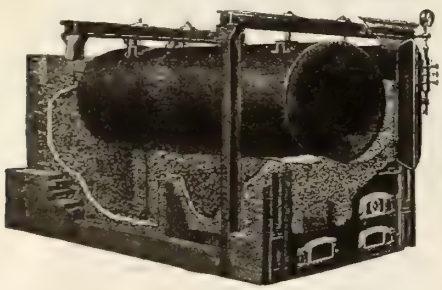

Illustration shows Betson's Plastic Fire Brick Lining, including fire box, front wall of arch, furnace side walls, bridge wall, combustion chamber walls and rear arch.

Betson's Plastic Fire Brick can be used to construct entire linings in place of fire brick, or to repair and replace defective linings of ordinary brick. It is practical for all types and makes of boilers. Also baffles can be built of any size, shape or slope, for horizontal or vertical type boilers of any make.

Easy to lay up—no special tools needed—shipped ready for use—from warehouses in many cities. Backed by a service record of over 20 years.

If it's "Plastic Fire Brick" it's Betson's. If it isn't Betson's it isn't "Plastic Fire Brick."

Write for our informing Booklet to-day.

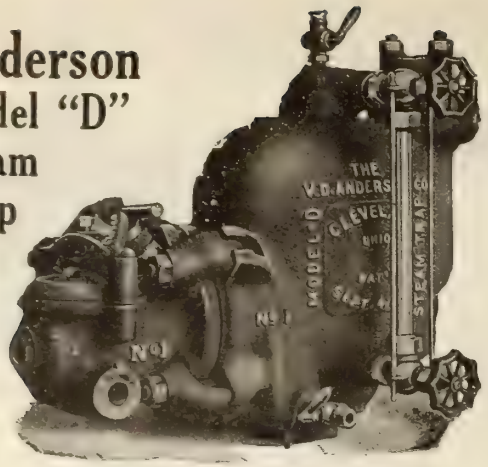
Anderson Model "D" Steam Trap



Different —and Better!

In the Anderson Model "D" Steam Trap you have the answer to your condensation problems. Its unique construction fits it for use anywhere. It automatically disposes of the condensation as fast as it accumulates and adjusts itself to any varying amounts within its capacity.

To change from high to low pressure or vice versa, all that is necessary is to change the valve and valve seat. This can be done in five minutes without disturbing or unscrewing a single joint or pipe connection.

The valve seat is always sealed with at least three inches of water, making the escape of live steam impossible, which means not only a saving in time and trouble, but what is more important, a great saving in coal.

Special features of the Anderson are, a self-contained strainer, an outside gage glass, self-contained by-pass and complete accessibility to all parts.

Install one on that 120-lb. main—to protect the engine; on these 60-lb. coils in the vacuum pans; on those big exhaust heaters under the drying ovens, anywhere where there's condensation to handle.

Booklet and prices on request

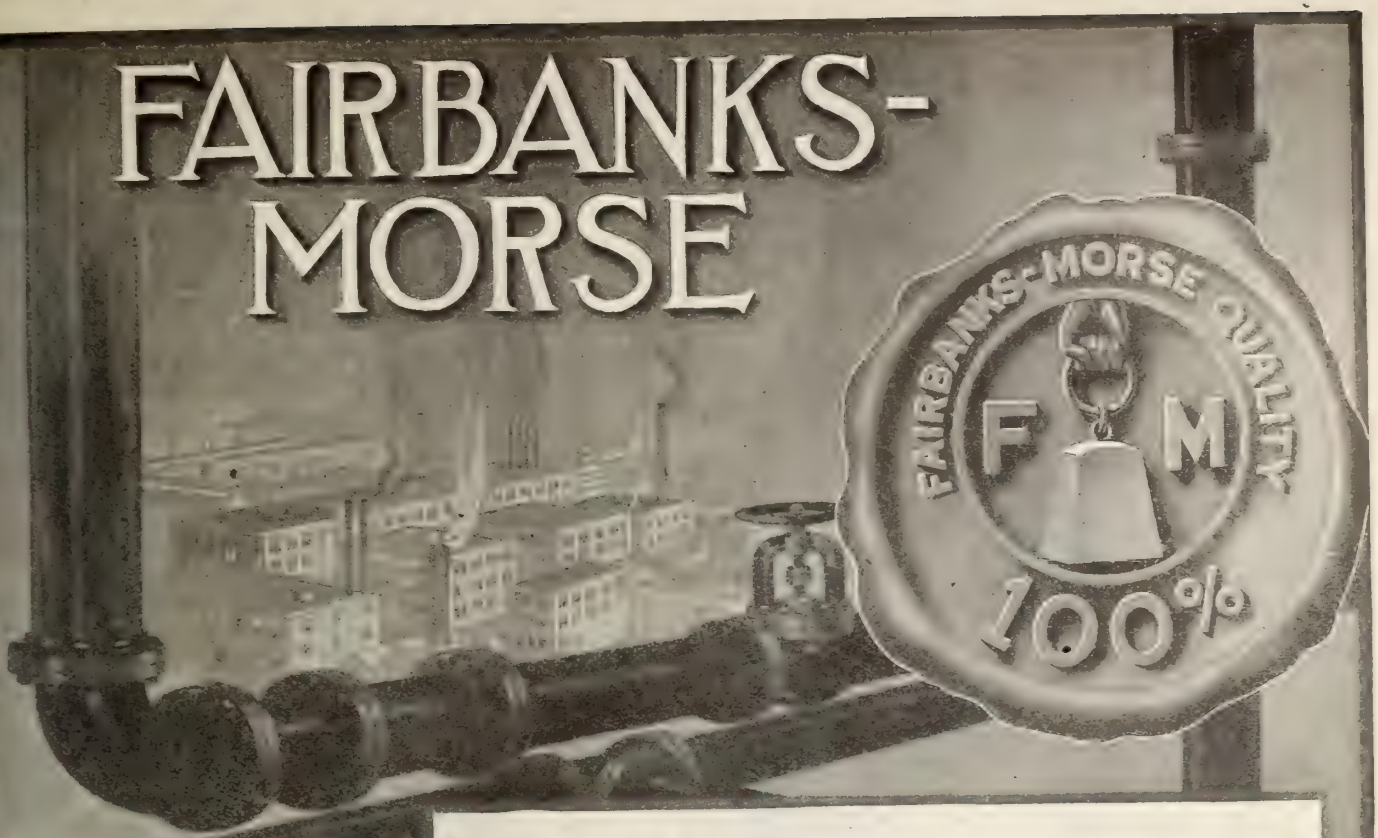
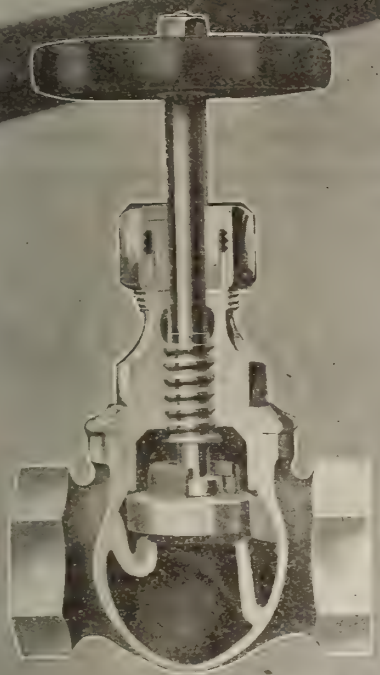
FAIRBANKS-MORSE





An Achievement in Mechanics

EACH individual department of The Canadian Fairbanks-Morse Company, Limited has given industrial Canada a new conception of achievement in mechanics. Each department has established a 100% quality and service standard. This is what enables Fairbanks valves to stand pre-eminent wherever valves are used.

When an engineer specifies Fairbanks valves, he knows that he has selected not only quality of material but workmanship that guarantees perfect operation.

He is satisfied with the reputation and service of the institution that stands behind them. He acknowledges an achievement in mechanics.

Wherever pipe lines are laid—in Canada's great industrial plants—in her immense water systems—in mines and mills—Fairbanks valves are giving a service that is marked by the 100% seal of quality, the standard of The Canadian Fairbanks-Morse Co. Limited.

Our nearest branch will give you the benefit of this service, Our experts will help you in selecting valves and everything mechanical that you require. Make our catalogue your buying guide.

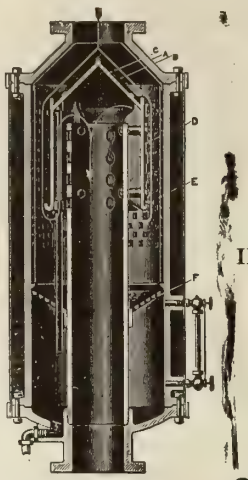
III IMPORTANT THINGS
TO CONSIDER ABOUT A SEPARATOR



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE — Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION — Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

DURABLA

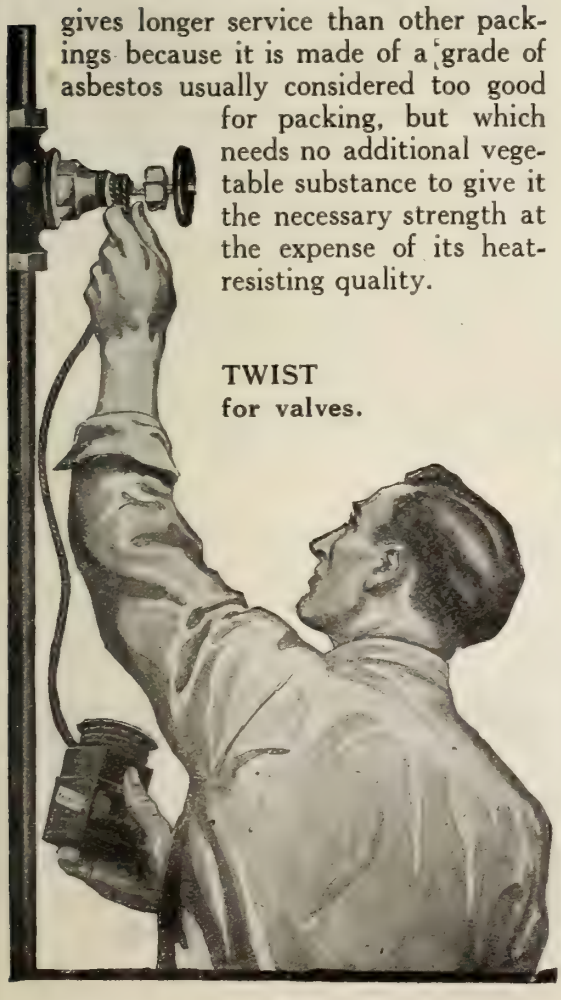
The Question of ECONOMY

OF A ROD PACKING LIES IN THE LENGTH OF SERVICE, AND NOT ITS FIRST COST

"PALMETTO"

gives longer service than other packings because it is made of a grade of asbestos usually considered too good for packing, but which needs no additional vegetable substance to give it the necessary strength at the expense of its heat-resisting quality.

TWIST for valves.



"PALMETTO"

does not become hard like other packings, because each single strand has lubricant forced into it before braiding, which lubricant not only keeps it soft but so lubricates the rod as to prevent friction and wear of both rod and packing.

BRAIDED for rods.

Let us send you sample of both braided and twist to test—no charge.

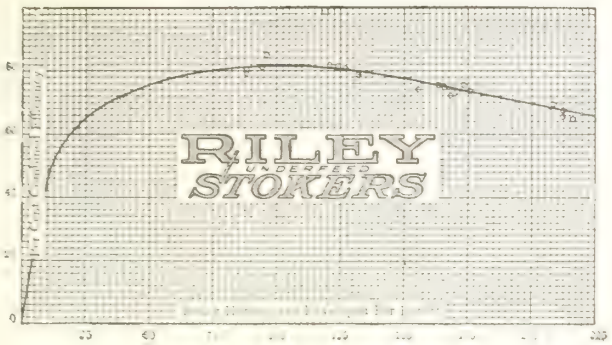
High Efficiency



The continuous high efficiency of the Riley Stoker is due to the moving grates. These moving units not only keep the fuel bed open, porous and free from clinkers, but automatically discharge the ash and refuse.

Because of the moving grates, Riley Stokers have that faculty of operating continuously at high efficiency and capacity. Fuel-saving is a mechanical certainty. There can be no waste.

The efficiency curve shown above is typical of Riley Stoker performance. This curve is plotted from a series of tests conducted on a 16-retort Riley Stoker installed at the Essex Station of the Public Service Electric Company, Newark, N.J. Why not duplicate these results in your plant? You can do it with Riley Stokers.

Riley Stoker catalog HR-8 sent on request.

For information on the Murphy Automatic Furnace for smaller boilers, see last month's advertisement, or send for Murphy catalog HM-8.

Sanford Riley Stoker Co.

"Jack—why don't you save yourself work and save the boss money by using

PRATT & CADY RENEWABLE VALVES"

You'll be an enthusiastic booster for these 20th-century valves if you give them just one trial.

They save work for the men, because they don't have to be ripped out of the pipe line and replaced with a new one when they wear and begin to leak. New seat rings, or a new disc, can be inserted in a few minutes.

This makes the old valve as good as new at about 10% of its original cost. That saves the boss 90% of the cost of a new valve—saves the time of men removing an old valve from line and putting in a new one—and often saves shutting down part of the plant while a new valve is being put in.

P & C Renewables are made in both Gate and Globe Valves, for every purpose. May we send booklet?

DEPARTMENT OF LABOUR

Ontario Government

Minister: Hon W. R. Rollo — Deputy Minister: W. A. Riddell, Ph.D.

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a **Stationary** steam plant of 50 B.H.P. or over, and everyone operating a **Hoisting** steam plant working at a pressure of 20 pounds or over, irrespective of horsepower and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a certificate from the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

All applications should be mailed to the Chairman of the Board. W. C. McGhie, Department of Labour, 15 Queen's Park, Toronto.

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering, the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., ch. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, 15 Queen's Park, Toronto. D. M. Medcalf, Chief Inspector of Steam Boilers.

Decrease Your Operating Cost

Efficient transmission equipment is an important factor in keeping down operating costs. Each repair you have to make to your belting equipment means delays and idle employees—the total cost of which is often greater than you would pay for better belting.

Dominion Friction Surface Belting

is built for "service first." Through its long life and continuous performance it practically eliminates the necessity for repairs and replacements. It eliminates delays and needless waste of time.

At your convenience, our belting experts will be glad to analyze your transmission equipment and prove that you can put in the profit column most of the losses created through transmission troubles.

All you need to do, is 'phone, wire or write our nearest service branch.

91

Continuous service and low maintenance cost due to the self-cleansing seat

LUNKENHEIMER "DURO"
BLOW-OFF VALVES

Remain tight under the most severe operating conditions because the self-cleansing seat feature eliminates the cause of most of the wear to which Blow-off Valves are subjected.

This self-cleansing seat feature,—exclusive in Lunkenhiemer "Duro" Blow-off Valves, functions automatically when the valves close by cutting off the inlet and allowing only a fine spray of water to pass, thereby removing foreign substances which may have lodged on the seat during the blow-off period.

In addition to the self-cleansing seat feature, the disc is reversible and has seat faces made of a durable alloy which readily accomodates itself to any irregularity in the seatring insuring tight though easily operated valves.

To further enhance their durability as a whole, all the parts are renewable.

Lunkenheimer "Duro" Blow-off Valves have proved their merit in service and are specified where boiler mountings of the better grade are desired.

All standard sizes, in material combinations to suit a wide range of pressure and temperature conditions.

Your local dealer can furnish them; if not, write us.

SINCE 1862

One sixteenth — one eighth —and more

NOT true?

Yes, it's an absolute fact when you compare ordinary rubber sheet packing with Seigelite.

Suppose you've made up a joint with sixteenth inch flange to flange distance. What thickness rubber sheet did you use? Eighth inch, of course, and squeezed it down to a sixteenth.

For the same job you could use sixteenth inch Seigelite and have a better, tighter joint in the bargain. You'd have a gasket that wouldn't rip or squeeze out—that would far surpass rubber on water service—that could be used against gasoline, benzene and other solvents where rubber or rubber substitutes would absolutely fail.

Other Johns-Manville Power Plant Materials: — Asbestos and Magnesia Pipe and Boiler Insulations, to reduce radiation and heat loss from uninsulated heated surfaces in power plants, public institutions, private residences, etc.; Packings for engines, pump and valve rods and pipe joints, to prevent steam leakage and power loss; Steam Traps to collect condensation without leakage of steam; Refractory Cements to lengthen the life of boiler settings and prevent setting leakage; and many other power plant maintenance materials.

Canadian Johns-Manville Co., Limited

Toronto Montreal Winnipeg Vancouver
London Hamilton Ottawa Windsor

Give these facts a thought the next time you start to order rubber sheet — for water, oil or gasoline service — and change it to Seigelite, the thinner packing for better service. Seigelite is dense but resilient before it is squeezed between flanges.

KELLOGG CHIMNEYS

Kellogg represents the most advanced idea in chimney construction.

Tests have proven that the adhesion between mortar and Kellogg Corrugated Brick is 62½% greater than between mortar and ordinary straight or plain-sided brick.

Molding Kellogg Bricks with vertical perforations permit thorough burning, thus increasing their density and strength, and decreasing their weight.

Kellogg chimneys are the logical selection for your power plant. Their stability and permanence offer a great advantage over other chimneys.

You should be thoroughly familiar with the many features of Kellogg Chimneys. Let us send you full details.

CHAPTER I

COMBUSTION ENGINEERING

How the new chief met the problems of fuel economy and plant efficiency

Jim Payne had been chief engineer of the Great Western Hotel for nearly twelve years. Just now, however, he was sorely peeved; he had asked for an increase in salary and had been turned down. As a consequence he had tendered his resignation. The manager had refused to give the desired raise because he was not quite satisfied with the manner in which the operating costs were piling up. Of course, fuel, oil, materials, supplies and other expenses had gone up nearly every day, but the manager was not satisfied with the statement that some improvement could not be made.

When Payne tendered his resignation the manager asked him to recommend a man for the place. He recommended the young assistant chief, who had been in charge of the detail work and most of the repairs for nearly three years.

"It's up to you now to make good," Payne told the assistant when he informed him of the latest move. "I guess I have let my years get away from me without taking advantage of the opportunities there are for the man who knows Combustion."

That morning the general manager of the hotel called the assistant into his private office for a short talk. "These are serious times," he said, "and every power plant owner, like myself, must look forward to greater saving in fuel. There is a real opportunity here for the man who knows or the man who will study Combustion."

The new chief readily saw that the new job called for more brain work than physical work and "*it was evident that employers were willing to pay more for a strong mind than for a strong back.*"

Presently the new chief wandered back to his desk and extracted a large report or dope sheet. On this he began to write a thousand and one questions about the plant, directed at himself. He was cross-examining himself, much as a shrewd lawyer would examine a witness on the stand.

The questions ran something as follows:

WHAT are your chances for real success?

Do you realize the opportunities that a knowledge of Combustion offers to the man who wants to be more than merely the average?

It is not so much a strong back today as it is a strong mind that counts!

The man who knows Combustion can state his own salary and his services are always in demand.

Would you like to have the opportunity of getting a thorough knowledge of Combustion and Boiler Room Management in your spare time and at a very small cost, payable monthly if so desired? Jos. W. Hays, author of the Course and Educational Director, formerly Consulting Combustion Engineer of the U. S. Navy; W. L. Abbott, Chief Operating Engineer of the Commonwealth Edison Company; Fred R. Low, Editor of "Power"; Prof. S. W. Parr, Department of Chemistry, University of Illinois; Joseph Harrington, formerly Administrative Engineer, U. S. Fuel Administration; David Moffat Myers, formerly Advisory Engineer for the U. S. Fuel Administration; Arthur L. Rice, Editor of "Power Plant Engineering," and I. E. Moultrop, Bureau of Construction, Edison Electric Illuminating Co., have now made it possible for you, thru the Hays Course in Combustion Engineering and Boiler Room Management, to obtain a thoro knowledge of Combustion in your spare time without interfering with your present work in the least.

This Free Book

will tell you some interesting pointers that the average power plant and boiler room man should know, particularly about Combustion Engineering

The coupon will bring to you, without any expense whatever, a copy of this interesting book, covering power plant and boiler room management. It tells you how other men like yourself have, thru the Hays Course, achieved real success and how the same can be made possible in your case.

If you are determined to get out of the ordinary class and to push ahead where your services will be worth much more than they are today, get your copy of this book at once. It will help you from the time you receive it. It will interest and inspire you because it shows a better way toward bigger things. It also shows how, thru the Course, in addition to obtaining a knowledge of Combustion, you get, as well, a liberal education, paving the way for real executive ability.

Your request for this book will obligate you in no way whatever—merely clip the coupon below and return it today with your name plainly written or typed. Promptly upon receipt of the coupon the book will be sent you—absolutely FREE.

Industry Needed *Better* Hose —and Goodyear Built It

GOODYEAR Industrial Hose is built to meet modern industrial needs. Built as though hose had never been built before.

Breaking away from accepted but antiquated methods of hose building created Goodyear Industrial Hose —a hose that gives longer, more satisfactory service under present-day industrial conditions, and costs less in the end.

Water, Air Drill, Pneumatic Tool, Steam, Fire Hose—Goodyear studied and created a particular hose to meet the most exacting standards of each of these.

In the case of Steam Hose, Goodyear has done away with the inconveniences due to wire-winding—a choked hose due to bent wire, bulges and blisters under pressure; a racked tube and weakened fabric; the inconenience of cutting into shorter lengths, the utting of the hose by the wire.

Goodyear has made wire-winding on steam hose unnecessary, by developing a hose fabric strong enough to resist high pressure without the addition of wire. Compounded an inner tube capable of withstanding the effects of high-pressure steam. Fitted the hose with a tough, durable cover. Created a steam hose that will meet the severe conditions under which it is used—at a very low final cost.

Let a man trained by Goodyear in hose problems call and explain them to you. No obligation. Phone, wire or write the nearest branch.

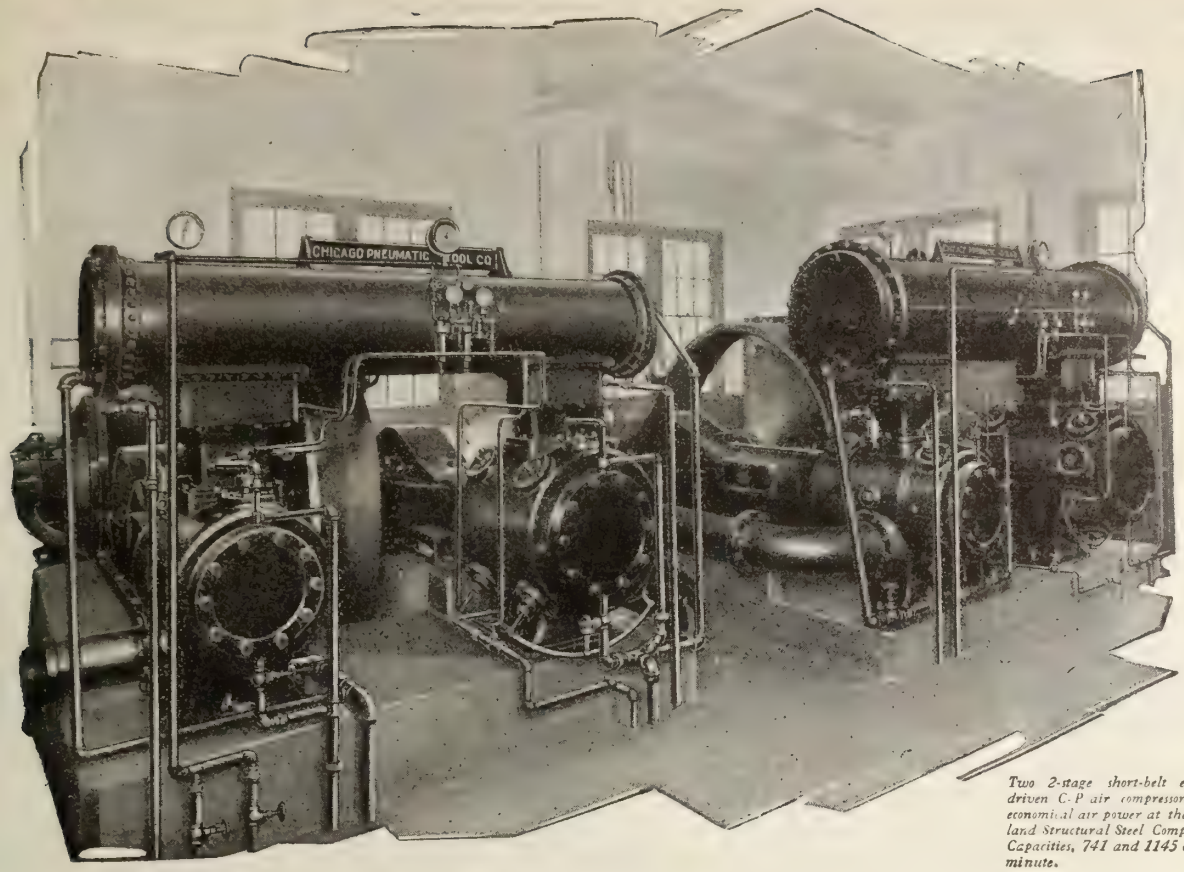
GOODYEAR
MADE IN CANADA
INDUSTRIAL HOSE



Two 2-stage short-belt electric motor driven C-P air compressors, delivering economical air power at the New England Structural Steel Company's plant. Capacities, 741 and 1145 cubic feet per minute.

Does your compressor work against a vacuum?

NOT if it's a Chicago Pneumatic Stage Type Compressor!

With no auxiliary valves, cylinders, chambers or valve gearing, the unloading system of these machines provides *economical operation from full to no load.*

Under all load conditions the cylinder ratio is unchanged, insuring constant power economy.

Under no load, the inlet valves are held open, permitting *free passage of air.* A distinct power saving is thus obtained over compressors using a "choked intake," with consequent power losses due to the partial vacuum against which they must operate.

If your compressor is unloaded ouly one minute every hour, this *one* exclusive Chicago Pneumatic feature will save you many dollars monthly.

Know *all* the money-saving features of the "Compressor with the Simplate Valve." Ask for Bulletin 400.

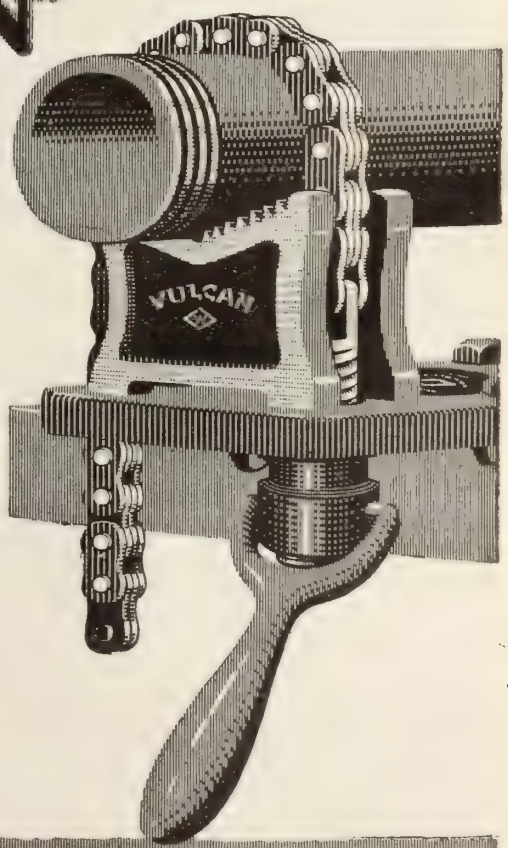
WILLIAMS' "VULCAN" DROP-FORGED CHAIN PIPE VISE



A PIPE vise, like any tool intended for rough usage, should be so designed and constructed that the severe strains and stresses of hard, continuous service cannot cause breakage or failure in operation.

Williams' "Vulcan" Chain Pipe Vises have no weak parts to fail through faulty design. Though they are far lighter and cost less than the conventional cast pipe vise, they are unbreakable. These Vises are made entirely from wrought metal, tested in our Laboratories before used. Each Chain is hand made.

Nothing that engineering experience and technical skill can suggest to improve them is omitted in thier manufacture. All are backed by our unconditional guarantee.

Three sizes for ⅛ to 8" pipe. Booklet on request.

JEFFERSON

"Look for the Name on the Nut"

Test a JEFFERSON on your Toughest Job

You must actually try out a JEFFERSON before you can realize perfect union service.

Jefferson Unions are unique in construction and are protected by basic patents covering the essential features. The Brass Seat Ring makes a tight **brass-to-iron** joint which cannot corrode and is easily disconnected. The Spherical Ground Joint takes care of alignment difficulties and makes possible a tight joint even if the line is not exactly straight.

Your Jobber has Jefferson stock. Order yours to-day. You can always tell them by the name on the nut. **Write for our catalog "Unions."**

A Big Factor in Every Factory is the BELTING

EXPERT care in Manufacture is necessary to produce a rubber belt, at once durable in quality, constructed to avoid fatigue in service and cured under necessary strain to eliminate undue stretch.

"P.M.S." BELTNG

is an assurance of steady, full transmission of maximum power. If you have a belting problem, submit it to our expert; his advice is worth while.

Cutting Costs By Saving Fuel

Elesco Superheaters will solve the problem of high fuel cost in your plant.

This saving is possible for you regardless of the product you manufacture, or the type and size steam plant you operate for power.

Fuel is too great an item in your manufacturing costs.

Made in Canada

THE ELESCO SUPERHEATER

applied to meet your operating conditions, will enable you to meet your production schedule on less fuel.

The fuel saving ranges as high as 25 per cent.

It will pay you to outline your fuel problem to our Engineers. They will gladly suggest a practical means by which you can cut the cost of operating your power plant.

Write for Bulletins.

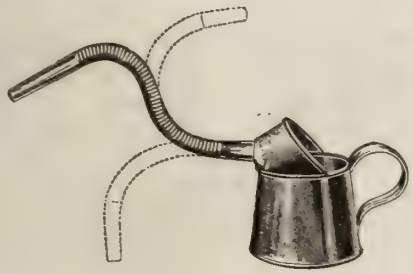
Say Good-bye to Funnels Use this 'ALL-WAY' Oiler



Combination Filler and Funnel

This Filler eliminates the necessity of the use of a separate Funnel. With the Flexible Spout any part can be readil reached.

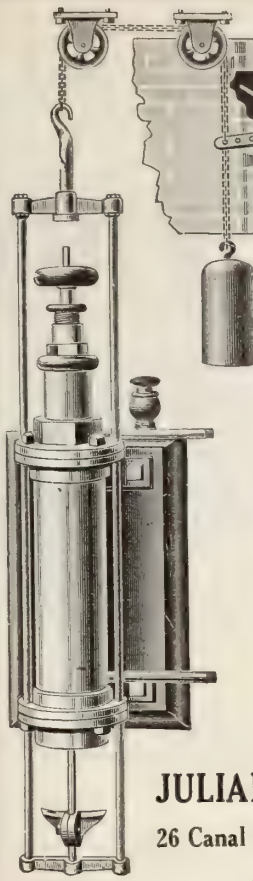
Saves much inconvenience and avoids dripping of oil.

If your dealer cannot supply you, write us.

We also manufacture the well-known "All-Way" Oil can. Saves you 50% of your oil bill.

THE ALL-WAY OILER MFG. COMPANY

196 King St. West Toronto, Ont.



Save Fuel

Fuel is scarce. Don't waste it. With the slightest variation in pressure the damper is automatically regulated in either direction by the

CURTIS

Improved Damper Regulator

It is a simple, durable and effective device. Positive and automatic in operation.

Write for our 1920 catalog showing the Curtis line of Engineering Supplies.

Canadian funds are accepted at par at Montreal.

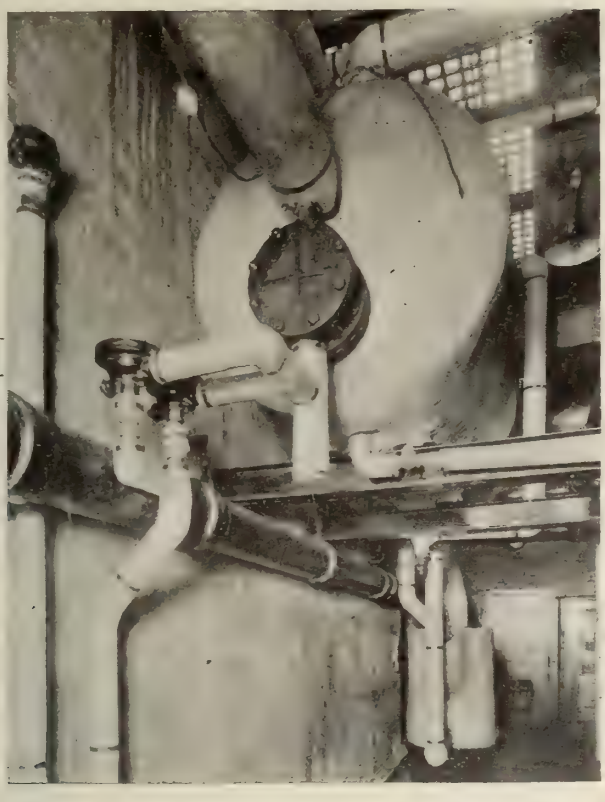
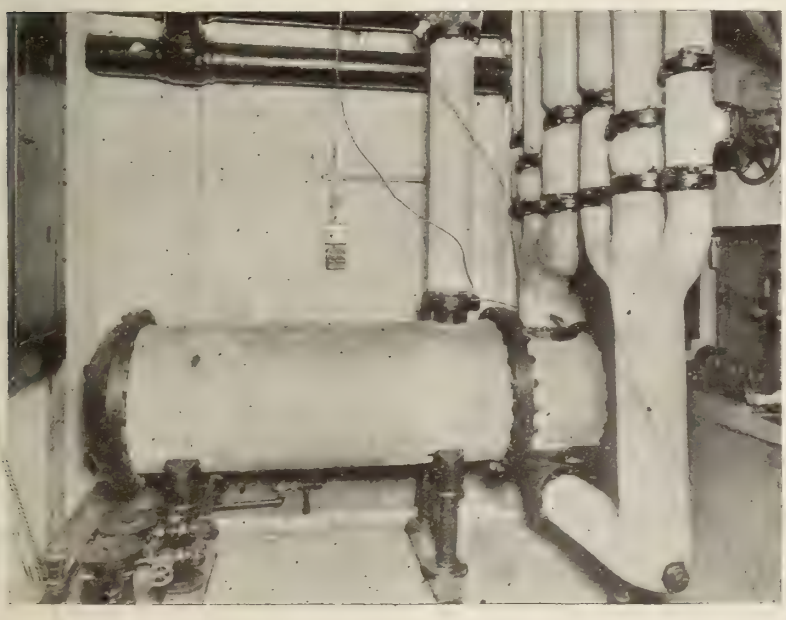
Sims Steam Tube *Water* Heaters



THERE are advanced features of design embodied in **Sims** heaters which distinguish them from other heaters—and **Sims** heaters are as superior in their service as they are different. **Sims** embodies straight tubes, 1½ in. O. D. Seamless Brass, rolled into a fixed head at one end, and a loose or floating head at the other. The tube structure is thus in no way attached to the heater. This construction admits of expansion and contraction of tubes without strain. Another feature is seen in the manner of grouping the tubes, which promotes the rapid circulation of water and allows for the best results in extracting the heat. **Sims** heaters have several other advantages. It is these advantages that have made **Sims** equipment preferred where large quantities of hot water, with live or exhaust steam as the heating water, are required.



The illustrations show Sims Water Heating Equipment at "Ardwold." Sir John Eaton's residence, Spadina Road, Toronto.

The upper illustration shows a 42 in. x 108 in. Sims No. 6 B.H. Clean E-Z Type Storage Heater for the Domestic Hot Water Supply. The lower illustration shows the Sims Converter, which supplies the swimming pool at "Ardwold."

For full information regarding Sims equipment write to—

Entered as second-class matter at the Post Office Department, Ottawa, Canada. Entered as second-class matter July 1, 1912, at the Post Office at Buffalo, under the Act of March 3rd, 1879.

WHY "MASON"?

Mason Standard Bronze Reducing Valve

THE splendid reputation of the Mason Engineering Equipment is not the result of an accident, but the expected outcome of forty years of persistent effort backed by large capital and superior manufacturing facilities.

They hold the first place to-day because their merits entitle them to that position.

No other devices work so accurately, wear so long, nor accomplish their purpose so fully as the Mason. Once installed they are always demanded thereafter, and thousands of manufacturers absolutely depend on these devices working in many critical locations and find them satisfactory. This is where Mason Service comes in. We have at your service a staff of engineers, specialists in the application of our devices. Their job is to see that you do not throw money away on unsatisfactory equipment, and to help you to choose equipment that will do the work required.

The Supreme Test—Service

THERE is only one test for a lubricant and that is "service"—service rendered under service conditions. The full benefit from capital sunk in expensive machinery can only be reaped through *correct* lubrication—*the best lubricants properly applied.*

Imperial Lubricants need no introduction. They are known and used from coast to coast. They are graded for every type of machine; are Canadian made from the finest crudes and readily obtainable in all parts of the Dominion.

Choose your lubricants from the Imperial line. Take advantage of our offer of free consultation. Both aim to assist you to insure that production shall bear a true relation to the time, thought and money expended in equipment.

Correct lubrication means the selection and proper application of the right lubricant for each machine. Correct lubrication actually promotes maximum profits, increasing production per unit and decreasing depreciation charges, fuel and repair bills.

Imperial Lubrication Engineers are at your service for consultation in solving troublesome lubrication problems. Their advice is free. Write to us at 56 Church St., Toronto, or to any of our branches.

WORTHINGTON S. D.
DOUBLE VOLUTE PUMP

"See our exhibit at the Sixth National Exposition of Chemical Industries, Grand Central Palace, New York, week of September 20th"

—another example of Worthington utility and efficiency

FOR general service in and around coal mines, there is no pump that enjoys a more favorable reputation or renders a more complete pumping service than Worthington S.D. Double Volute Pump.

For fire protection, for heads above single impeller limits, for unwatering mines—this pump can be standardized on, and because parts are interchangeable, repair bills and time losses are reduced to absolute minimum.

Simplicity of design is attained by using the double volute feature which eliminates diffusion rings, and because impellers are "back to back" there is no end thrust. This construction also results in minimum number of slippage points.

Worthington S. D. Double Volute Pump rounds out a full centrifugal pump service and typifies the wonderful 80 years old organization which sponsors it.

Other Worthington Products

Steam, Power, Centrifugal and Water Works Pumps. Meters, Oil Engines, Condensing Machinery, Air Compressors, Vacuum Pumps and Water Wheels.

To further enlarge their service, Worthington have acquired the goodwill and mechanical equipment of the Platt Iron Works, Dayton, Ohio, for manufacturing Oil Mill machinery, Hydraulic Turbines, Feedwater Heaters and High Pressure Air Compressors.

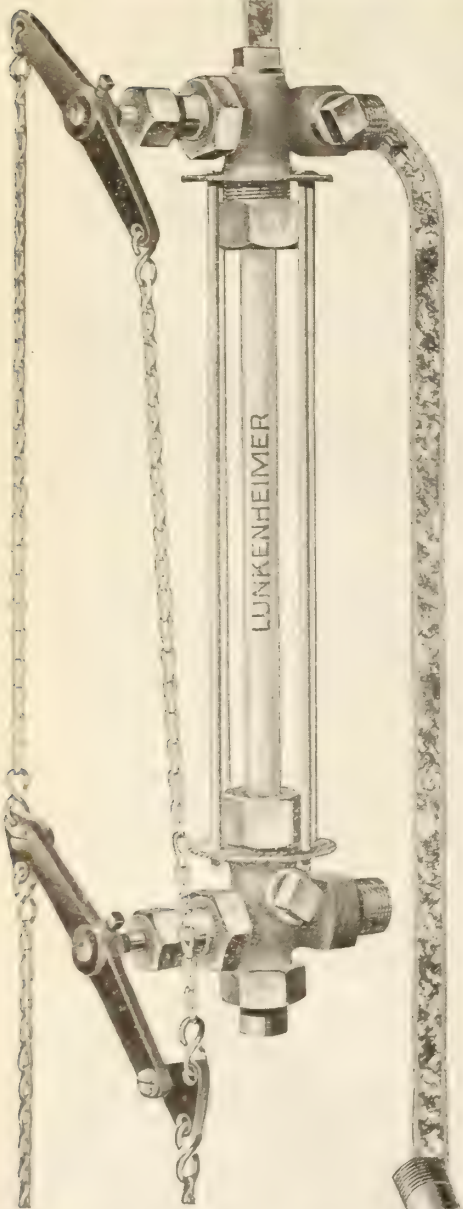
LUNKENHEIMER

WATER GAUGES, GAUGE COCKS AND FUSIBLE PLUGS



Absolute reliability in operation and maximum durability under the most severe operating conditions are the basic factors which govern the manufacture of LUNKENHEIMER WATER GAUGES, GAUGE COCKS, AND FUSIBLE PLUGS. These essential requirements, based on a thorough knowledge of operating conditions; the selection of proper metals for the specific requirements and Lunkenheimer "Quality" workmanship, have established the Lunkenheimer Line as standard for Safety and Economy.

Lunkenheimer WATER GAUGES are reliably accurate. The shut-off valves provide positive control in case of glass breakage and provision is made for the easy renewal of the glass should necessity require. Made in both Automatic and Non-automatic Patterns with Hand Wheel or Cross Lever Control.

Lunkenheimer GAUGE COCKS are substantial, positive in operation, and so constructed that a worn or broken part can easily be replaced. The variety of types made covers every service requirement.

Lunkenheimer FUSIBLE PLUGS are safety devices of merit. The fusible core is pure Banca tin and the Lunkenheimer method of filling the plugs precludes the possibility of chemical change during the process. This insures dependability in service Inside and Outside types in all sizes.

For Safety, Service, and Satisfaction specify LUNKENHEIMER and insist on their installation. Write for descriptive literature.

Every Power Plant Engineer Should Have This BOOK

LINK-BELT TRAVELING WATER SCREENS

LINK-BELT Traveling Water Intake Screens are a necessity in the modern power plant. They automatically remove all floating trash and debris, and insure a steady supply of clean water to the condensers. Uninterrupted operation is assured at all times regardless of the condition of water supply.

This book gives complete information. It shows what you can accomplish by atomatically screening water before it reaches the condensers. Use the coupon.

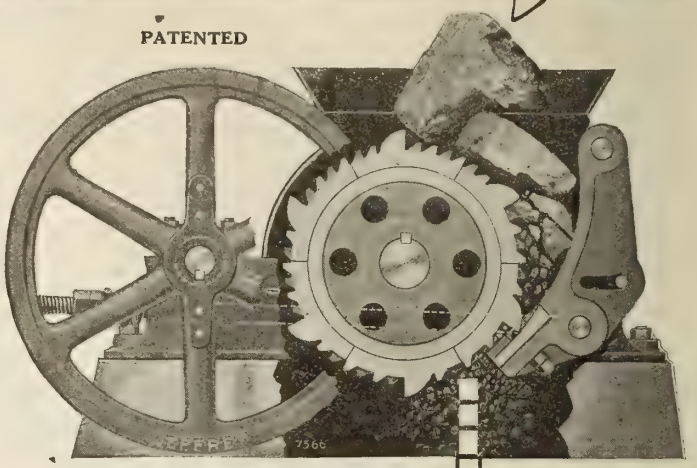
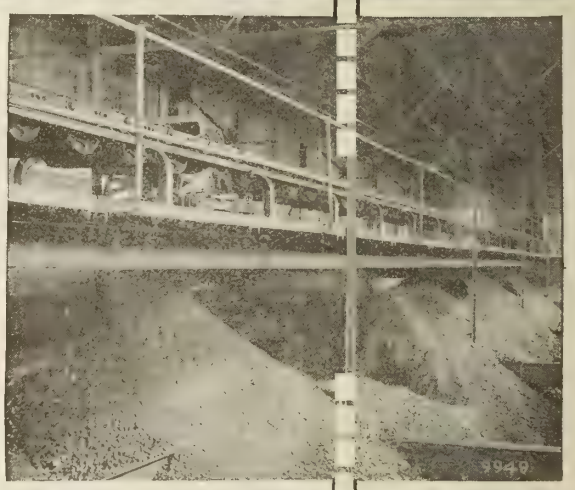
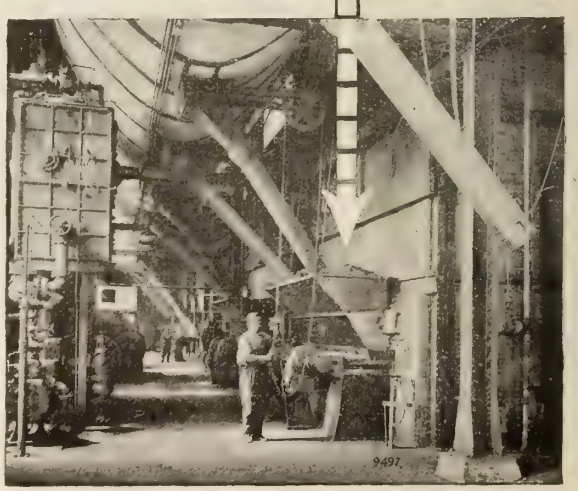
Run-of-Mine Coal Through A Jeffrey Single Roll Crusher

PATENTED







Will Insure Proper Sizes and Quality of Coal For Your Stokers

Run-of-Mine or Lump Coal give proper quality, but cannot be used in stokers without crushing. Mine screenings which are of the proper size at times cannot be secured.

The Jeffrey Single Roll Crusher installed at your plant will render it independent of the supply of screenings, and enable you to secure the maximum of stoker efficiency.

Bulletin No. 141-4 should be in the hands of every Manager, Superintendent or Engineer who is responsible for supply of properly sized coal. Send for copy.

The Jeffrey Mfg. Co.

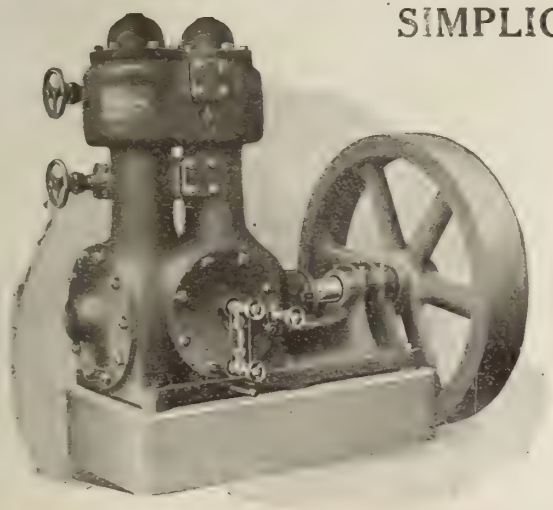
BURN ANY FUEL THAT HAS HEAT IN IT

York Enclosed Refrigerating Machines

SIMPLICITY—ECONOMY



After operating one of our Enclosed Machines for several years, one of our customers writes us that he has not spent one cent on it except for oil, and is still using the original charge of ammonia. This is a common experience among users of these Machines.

Simplicity of design and accuracy of construction permit them to be operated successfully by employees who, prior to the installation of these machines, never had any experience in operating one.

If you are finding the present scarcity of ice a burden to your business here is a simple and safe method of relief, and besides MECHANICAL REFRIGERATION pays good dividends on the investment.

Write us for information and prices.

Power Plant Firebricks

Conserve Heat and Cut Coal Bills

Increased boiler capacity and higher fuel economy are two of the advantages that follow the installation of Gates Power Plant Firebricks. They conserve furnace heat and permit a more even and more efficient condition of the fire to be maintained.

Gates Firebricks are easily installed in boiler linings and are so designed that when any part becomes fused a handy man can replace it in half the time it takes to repair a standard fire brick job. There is no possibility of costly air leaks and the many joints that clinkers stick to when ordinary firebrick is used are entirely eliminated. A complete stock of various sizes always on hand. Immediate shipments.

We specialize in all kinds of power plant brickwork. Boiler setting, Furnace building, Oven work and Repair Jobs. Get in touch with us!

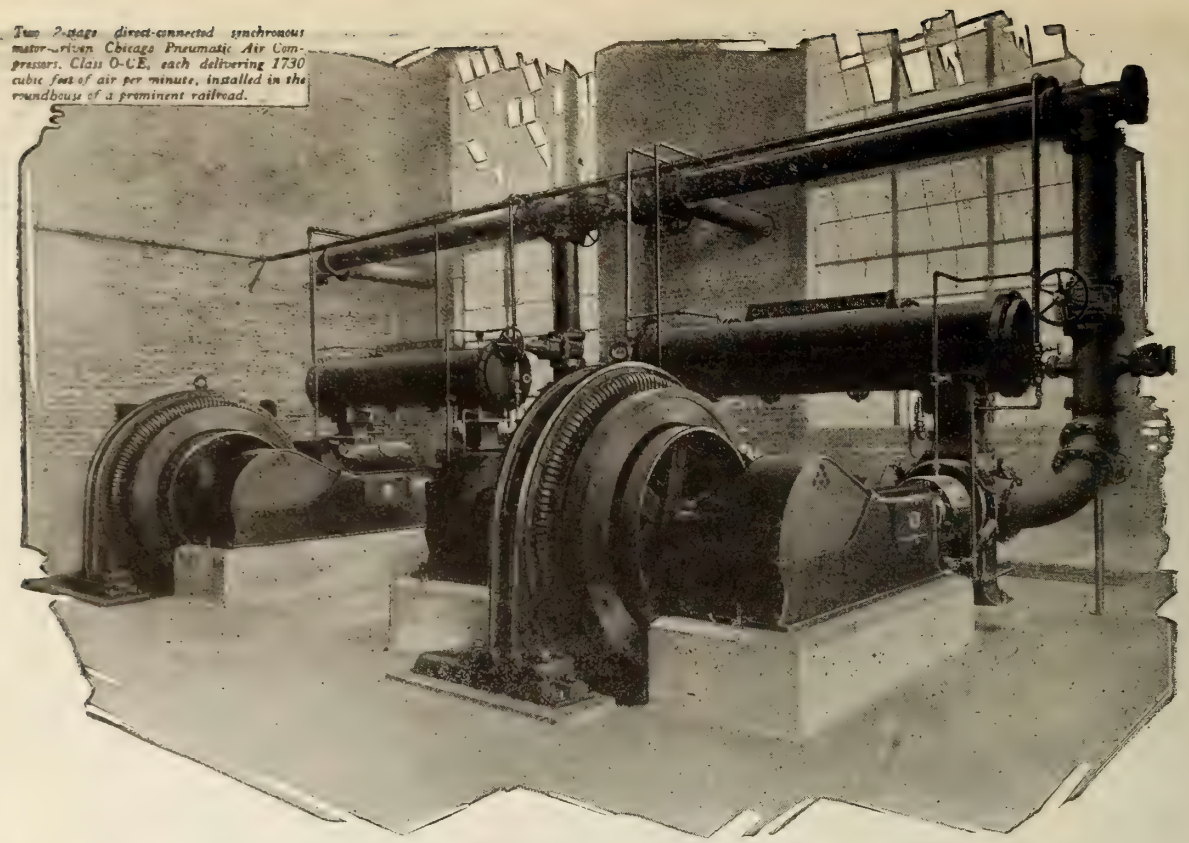
COPPUS TURBO BLOWER



Two 2-stage direct-connected synchronous motor-driven Chicago Pneumatic Air Compressors, Class O-CE, each delivering 1730 cubic feet of air per minute, installed in the roundhouse of a prominent railroad.

An unloading system that saves power

DOES your air compressor pull against a vacuum *after unloading?*

Not if it's a Chicago Pneumatic whose unloading system permits the *free passage* of air through valves automatically held open when maximum receiver pressure is reached.

This one Chicago Pneumatic feature saves marked power over compressors in which unloading by choking the inlet pipe means power lost through working against a vacuum after unloading.

Strict power economy *before* and *after* unloading, and economy of floor space, make the direct connected motor-driven compressor illustrated an ideal power unit for—

Railroad shops, shipyards, structural steel plants, cement mills, packing houses, mines, oil refineries, glass manufacturing plants, textile mills, and miscellaneous manufacturing plants.

Know *all* the advantages of Chicago Pneumatics. Have you read Bulletin 400?

12 to 300 H.P. at Speeds up to 1,600 R.P.M.

broken blades are not always poor blades.

Often it's a case of a good saw used in the wrong way. A hack saw may be brittle as glass or flexible as a watch spring, according to the temper of steel, but the temper is only one of the things that go to make good blades.

Starrett Hack Saws are tempered, milled and selected according to the work they are designed to do. That's why they "cut quicker and last longer."

According to the Starrett system of blade selection, there's a saw for every metal. Many saws will cut more than one metal, but no single blade will cut all metals, or even all shapes of the same metal economically.

Starrett Hack Saws plus the Starret Hack Saw Chart make it easier to cut metal economically. Ask for a copy of Chart CD—and "Hack Saws and Their Use"—both are free.

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**

BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Plastic Fire Brick in modern high stoker-fired furnace, including side and front walls, door arches, bridge wall and baffles

Seamless One-Piece Boiler Furnace Linings

Betson's Plastic Fire Brick is not a brick nor a cement, but a plastic compound of fire clays of highest refractory properties. It is properly proportioned to eliminate expansion and contraction and is used to build completely, one-piece furnace linings and to replace laid up fire brick, tile or moulded-brick linings.

BETSON'S TRADE MARK PLASTIC FIRE BRICK

is not high in price, it is high in efficiency. It is economical because it out-wears other linings and is so easy to install.

This plastic material is simply pounded into place with a mallet and smoothed with a trowel. No special forms, tools or training are required to execute a first-rate job.

With it tight, permanent baffles of proper size, shape and angle to form tapering passes, can be made for any type boiler, in your own boiler room, without disturbing your boiler setting.

Betson's is the pioneer and only Plastic Fire Brick. Backed by over 20 years' satisfactory service. Write for informing pamphlet.

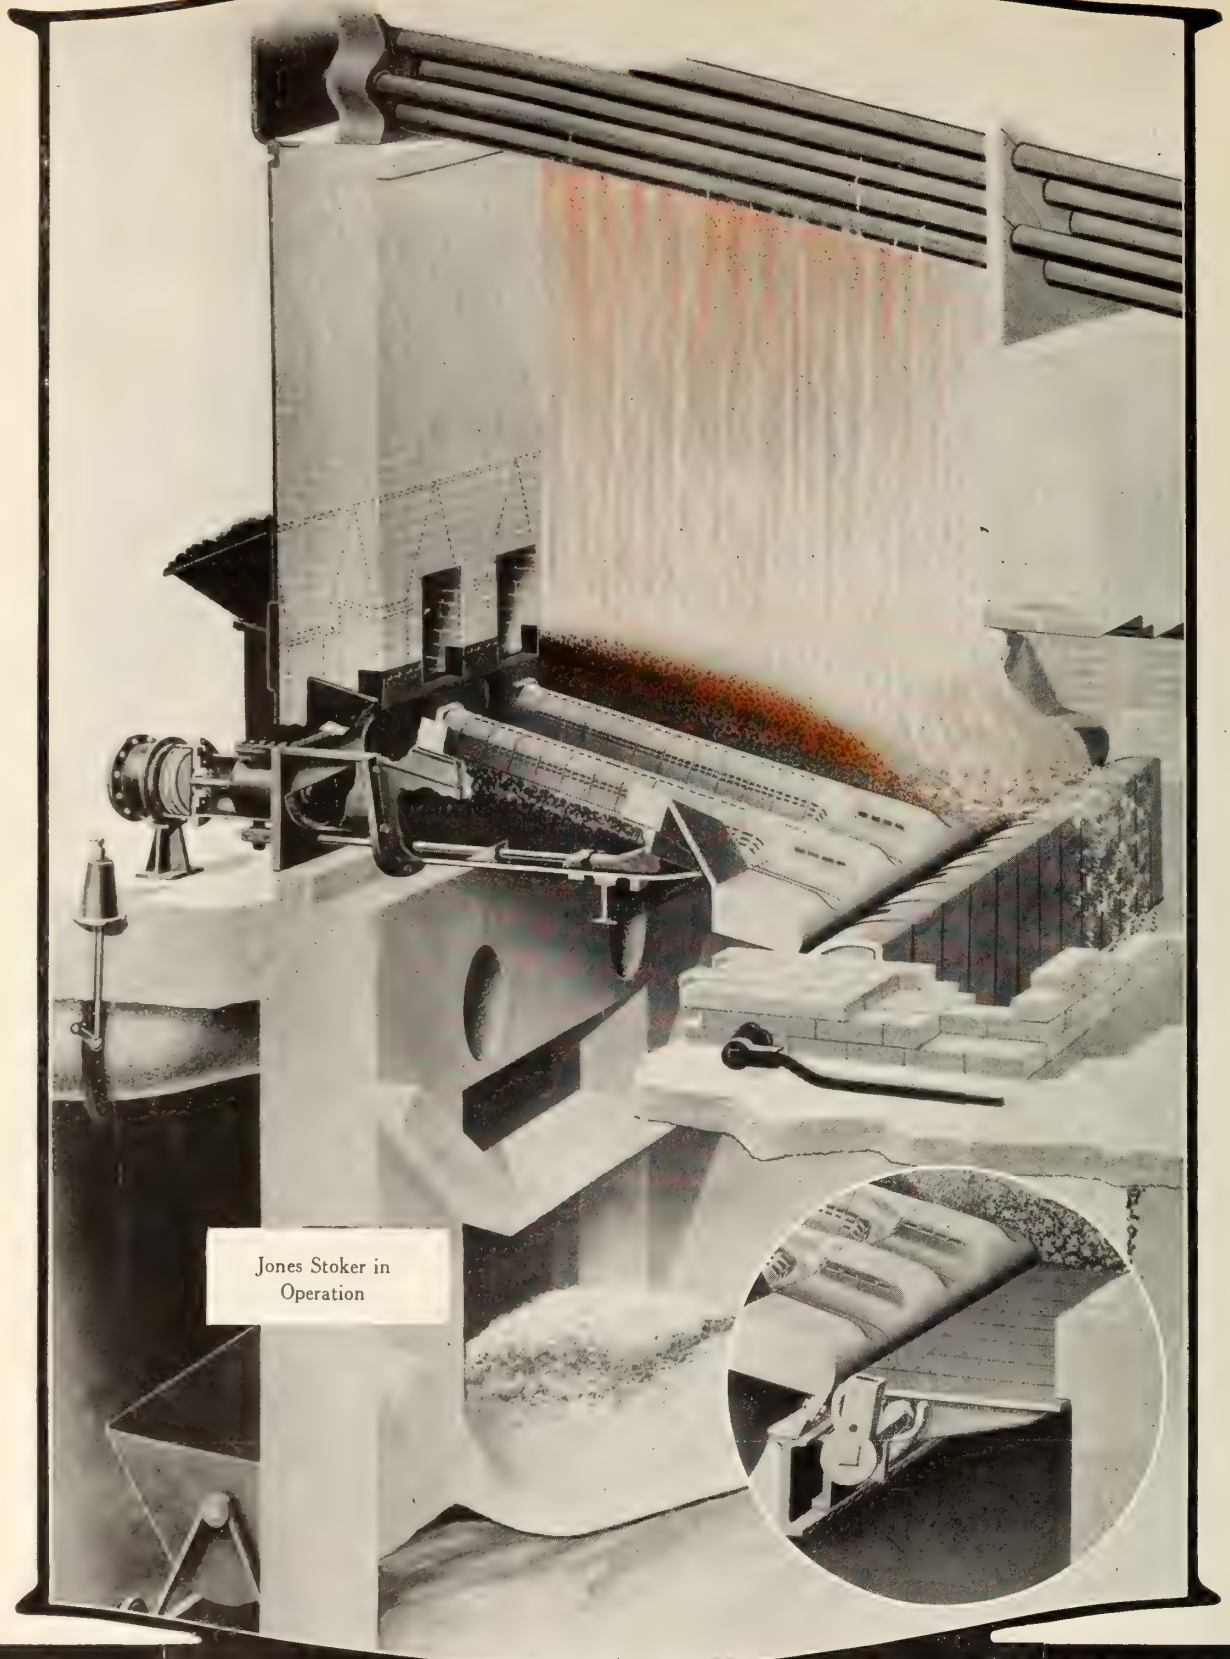
Jones "A-C" and "Standard" Stokers are described in the following pages—



Jones Stoker in Operation

The JONES

Jones Stokers

for Plants of Every Type and Size

Jones "A-C"

Automatic-Cleaning, — Automatically-Controlled

JONES "A-C" Stokers are high-duty stokers. In many large plants from coast to coast they are operating continuously at heavy overloads. The automatic-cleaning ("A-C") feature saves labor. No hand cleaning is necessary. Clinkers are not formed on furnace walls. Fuel and air are automatically supplied in the right proportion for complete combustion with highest economy. Fires are automatically kept in perfect condition. Coal consumption is materially reduced.

Write for a complete "A-C" catalog

Jones "Standard"

Jones "Standard" Stokers are suitable for smaller plants. They can be installed under any boilers without disturbing boiler setting. No excavations are necessary. Like the "A-C" type, they are extremely simple in design and operation. Few moving parts—none in the fire. Foreign matter in fuel cannot cause damage. No shearing pins used. Very low maintenance cost. Smoke is prevented. Automatic fuel and air regulation insures best possible economy without expert supervision.

UNDER-FEED STOKER

Made in Canada

The Service Behind the Stoker

THE Jones Under-Feed Stoker Company, Limited, has been reorganized, and its name changed to the Under-Feed Stoker Company of Canada, Limited. The following are the officers and directors of the Company:

President: Lloyd Harris, late Chairman of the Canadian Trade Mission, London, England; President Russell Motor Car Ltd.; President the Under-Feed Stoker Company of America.

Vice-President and General Manager: S. A. Armstrong, Vice-President and Managing Director of the Under-Feed Stoker Company of America.

Directors: T. A. Russell, President Willys-Overland Ltd.; Vice-President Russell Motor Car Ltd., and Director of the Under-Feed Stoker Company of America.

A. E. Holmested, Barrister, etc., and Director of the Under-Feed Stoker Company of America.

H. J. Fuller, President Canadian Fairbanks-Morse Company, Ltd.

David Fasken, K.C., President Excelsior Life Insurance Company.

This Directorate and reorganization makes available for all industrial Canada the engineering experience and development of mechanical stokers of the Under-Feed Stoker Company of America and the Under-Feed Stoker Company of Canada, Ltd.

This Canadian Company has carried on business in Canada for the past twenty years. Its stoker equipment is manufactured in Canada—is sold for Canadian money at par.

This is the only stoker company doing business in Canada to-day that is qualified from the standpoint of equipment to handle any type of combustion problem presented.

The Under-Feed Stoker Co.
of Canada, Ltd.

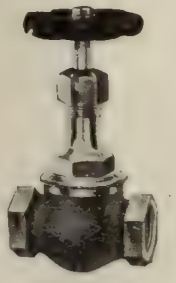
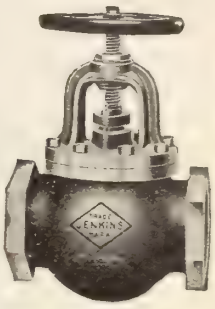
56 Years' Record of Success Throughout The World

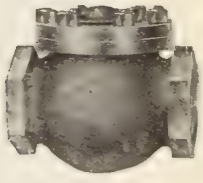
TRADE JENKINS MARK

The Jenkins Diamond Trade Mark is a Seal of Guaranteed Service

Jenkins Bros

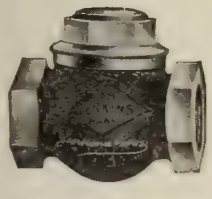






The Trade Mark That Says "This Valve is Dependable"

That is just what the Jenkins Diamond Trade Mark signifies—**absolute Valve Dependability.** It is cast upon the body of every genuine Jenkins Valve; put there as a protection against inferior imitations and a guarantee of lasting service under every condition of usage.



In every line of industrial endeavor—in power houses, water works, railroad shops, factories, office buildings—wherever good valve service is vital Jenkins Diamond Trade Marked Valves are giving a service in keeping with their 56 years' reputation.

Catalog No. 8, free on request, pictures and describes the complete line—A Valve for every purpose.

Obtain Jenkins Valves from dealers everywhere.

WAIT STEAM TURBINES

The Acme of Perfection

MANY recent improvements in detail by skilled investigators have resulted in the G. & McC. Co. "Wait" Steam Turbine reaching a high point in efficiency—it is in fact recognized by leading engineers as the acme of perfection in steam turbines. Some of its leading features include in addition to high efficiency—simplicity, ruggedness and economy of operation.

Points of this G. & McC. Co. Machine that should be remembered are:

—The Turbine is entirely automatic.
—No oil or grease cups.
—Stuffing boxes and glands, seldom require attention.
—Emergency governor and valve are entirely separate from main governor and valve.
—Interior may be easily inspected.
—Self-lubricating; dust-proof; dirt-proof.
—Speed can be changed while running.
—LOW RUNNING EXPENSE AND COST.

Experiments on a Conveyor-Feed Type Stoker

As a Result of Two Years' Experimental Work, a Stoker Which Will Burn Eastern Bituminous Coal Successfully Has Been Obtained—The Author Describes Them in a Paper Before the A.S.M.E.

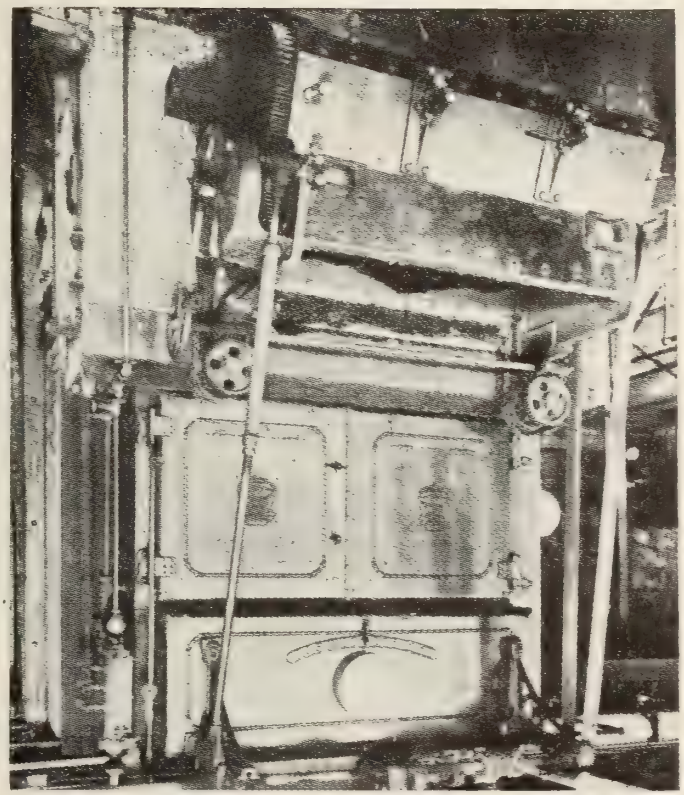
By LLOYD R. STOWE

FOR the past two years the Laclede-Christy Clay Products Company has been experimenting on a new forced-draft stoker for use with the various kinds of fuel found in this country. The boiler house of this company's Christy plant at 4600 South Kingshighway, St Louis, has been and still is being used for experimental, testing and development work. Fig. 1 shows the test boiler and stoker.

The burning of coal has always been a decidedly popular subject with engineers and naturally these two years of intensive experimentation have developed information that will be of interest to the members of this society. The stoker used employs the conveyor method of feeding, i.e., it uses progressively moving chain-grate conveying elements to feed the coal through the furnace and to discharge the refuse to the ashpit.

At the outset it is necessary that we realize the full import of the term "conveyor-feed." The conveyor-feed principle makes possible the use of grates that continually move onward in one direction. The fuel bed being supported on these moving grates is positively conveyed from the stoker hopper where fresh coal is introduced, to the discharge end where the refuse is rejected to the ashpit.

The feature of the conveyor-feed that commends its use is its handling of the fuel bed in a positive, definite fashion. By striking off the fuel evenly under a feed gate and then literally carrying it on through the furnace and over the point of ash discharge, this mechanism prevents in a large measure the evils of less positive feeding devices, namely, specifically uneven fires, balled-up spots, and immovable clinker formations. These advantages of conveyor-feeding are very attractive to the stoker designer, and as a result of this and of the fact that the underfeeds have quite thoroughly demonstrated the great advantages of mechanical draft, many builders are now experimenting on and developing various forms of forced-draft conveyor-feed stokers. In fact, work in this direction characterizes the efforts of the stoker industry at the present time, and the following particulars regarding the experimental work of the Laclede-Christy Company and the results it has attained should therefore prove of timely interest.



THE TEST BOILER AND STOKER.

It is well known that there have been many failures in attempting to burn eastern coal on chain grates. In fact, some have gone so far as to maintain that the undisturbed fuel bed of the conveyor-feed is so poorly adapted to eastern coal that it is useless to proceed further along these lines. Others have, in all sincerity, advised manufacturers to stay with the western coals, where the conveyor-feed rightfully belongs.

Now, one of the characteristics of the conveyor-feed, it will be observed, is that the fuel bed is undisturbed during the so-called coking period, or, more properly speaking, the period of destructive distillation. It is largely because of this feature that the author has elected particularly to relate what has been learned about eastern coals with conveyor-feed—coals high in heat value and low in ash and including those termed semi-bituminous and caking. And it may be as well to state at this point what may be considered as the conclusion of this paper: Namely, that the results of these experiments undertaken indicate that conveyor feeding can be used successfully with eastern bituminous fuels.

For many years it has been quite clearly established that nearly every re-

quirement of a successful stoker is lacking when burning caking fuels on chain grates with natural draft. The coal cakes almost immediately upon entering the furnace, high rates of burning cannot be secured, the combustible content of the ash is high, the admission of the air is not properly graduated to the requirements of the various stages of combustion, and maintenance of links is excessive. This is indeed a complete indictment, and with the sole exception that the automatic features are always in evidence, it may be said that the performance of chain grates on eastern bituminous coals violates every requirement of a successful stoker.

It is well known that the caking property of eastern coal is the most serious obstacle in the way of the successful use of this fuel on chain grates. In endeavoring to burn Pocahontas and similar coals it is observed that tarry oils flow through the fuel bed as a result of the application of heat at moderate temperatures. It is further observed that the coal under the arch is caked or coalesced by these tarry oils, and forms a sticky blanket that prevents the entrance of air through the coal and hence checks combustion and heat generation under the arch.

In attempting to remedy this situation the most natural thing to do is to employ mechanical means to break up the caked fuel bed, which is the course almost invariably taken by the inventor. In fact, the idea is prevalent that "A mechanical agitation of the fuel bed, for the purpose of breaking up the coke, is necessary or advisable when burning eastern coals." So many statements have appeared similar to the one just quoted that mechanical engineers have come to accept it as a basic fact. The results obtained at the experimental plant, however, have disproved this contention and in doing so have made possible the application of conveyor feeding to the burning of eastern coals.

Causes of Coke Formation in Stoker Practice and Its Prevention

All bituminous coals have a small resinous content that flows when heat is applied. In certain coals this resinous material has decided adhesive or binding properties and hence agglomerates the coal particles into a primary mass when it flows under the application of heat. This mass is the starting point of coke formation and out of it true coke may be formed by further actions that take place in the fuel bed. It must be noted here that while all bituminous coals have this resinous content its adhesive or binding property is lacking in the western, or free-burning coals.

It appears that the higher the oxygen content of the coal, the less pronounced will be the primary caking tendency. Analyses on a moisture-and-ash-free basis show that eastern coals contain less than half as much oxygen as do western coals of non-caking characteristics. Furthermore it is well known that eastern coking coals lose their caking properties by weathering, and it has been determined that weathering causes coal to absorb oxygen and to increase in weight by the weight of oxygen absorbed.

The absorption of oxygen can be accelerated and be made to take place in the boiler furnace by producing very high coal temperatures and accompanying these with a plentiful supply of air. In other words, this feature of weathering can be artificially carried on in an exceedingly short time. The oxygen absorbed apparently destroys the adhesive qualities of the resinous material referred to above and hence the primary mass from which the coke structure is later formed is not produced.

Again, when heat is applied to any bituminous coal, a chemical rearrangement or breaking down of certain of the compounds in the coal takes place. This action produces the greater part of what is termed "volatile matter," the remainder coming from the resinous content. The initial product of this chemical rearrangement is no doubt further decomposed into a fixed gas and a tarry residue. This tarry residue has not in itself the properties of a very strong binder, but it does build up and materially strengthen any primary coke structure that may already be present by leaving a film of carbon behind when the final breaking down into this carbon and fixed gas has taken place.

The foregoing theory accounts for the non-caking performance of eastern coals in the experimental work referred to in the present paper, and in its essentials seems to be the theory most commonly accepted by coal and coke analysts.

In the experiments with the new stoker the ignition temperatures are extremely high and at these temperatures considerable amounts of air are forced through the fuel bed, thus providing for the absorption of sufficient oxygen in a short time to destroy the initial caking tendency. Moreover, it is reasonable to suppose that these unusually high temperatures at the same time cause a quite different procedure during destructive distillation than that which obtains with lower temperatures. That is, these extremely high and unusual temperatures completely decompose both the resinous excretion and the remaining or major part of the volatile-forming matter before the former can set up an appreciable primary structure, and before the carbon of the latter can have time to impregnate any slight primary structure that may have formed.

The absence of coke formation changes completely the character of the fire under the arch and has almost as marked an influence on the last half of the fire because since coke is not formed in the distillation zone the cemented coke lumps cannot be present in the final stages of combustion. The individual pieces of coal retain their identity exactly the same as when Illinois coal is used, with the result that the fuel bed has the soft, incandescent and fluffy appearance which every chain-grate fireman realizes means economy and high rates of burning. The absence of coke formation in the final stages of combustion will be mentioned again.

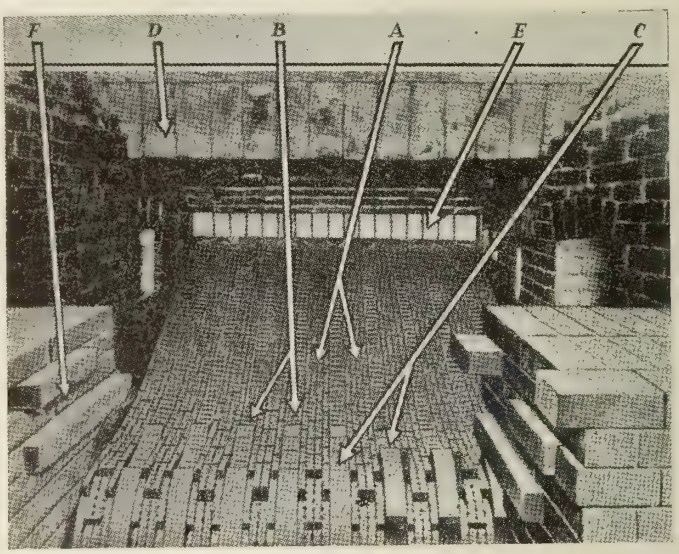


FIG. 2—VIEW OF THE GRATE SURFACE AND FURNACE TESTED.

The New Stoker

A description of the final apparatus decided on is advisable at this point for the purpose of showing how the high initial temperatures are obtained. Fig. 2 is a view of the grate surface, its general incline being 20 deg. The arrows indicated by A point to narrow chain grate or conveying elements, about 4 in. wide and placed on 7-in. centres. In the intervening 3-in. spaces are placed stationary tuyeres indicated by arrows at B. At the lower end of the grate surface the tuyeres B terminate in short pivoted bars C which are made automatically to rise above, then drop below, the surface of the conveyor chains. This action takes place slowly. D is a feed gate, adjustable to give various thicknesses of fire exactly as on a chain grate. Partly overhanging the vibrating bars C is the bridge wall E, shown cut away in the centre. An ignition arch

is shown at F. This latter provision conforms to chain-grate practice except that with the greater incline of the grate the arch is farther away from the fire. Fig. 3 shows a cross-sectioned side elevation of the stoker and boiler.

Close study of chain-grate practice has revealed much in the art of building up high ignition temperatures. A great expanse of bridge wall extending from a point horizontal with the arch to or nearly to the fuel bed is known to be of utmost value in directing heat on to the incoming fuel. This is the surface indicated by A in Fig. 3. The steep incline of the stoker in question permits this dimension A to be greatly extended over that possible with the ordinary chain grate. Moreover, it exposes the fuel bed more directly to the intense heat reflected from the bridge wall and the flame in front of it.

The form of arch was also taken from chain-grate practice and its design and placement has, of course, contributed its part toward the building up of the high fuel-bed and ignition temperatures that play so important a part in preventing the caking and ultimate coking of the fuel.

As to the admission of a generous supply of air (the second requirement for coke prevention), the greatest percentage of the total air supply is supplied under moderate pressure through that part of the fuel bed under the arch. This air supply, coupled with the very high fuel-bed temperatures obtaining, quite effectively destroys any inherent caking tendency of the fuels thus far tested, and made it possible to burn eastern coal with a considerable degree of satisfaction.

In view of the troubles known to exist with eastern fuels when using a stoker that conveys the fuel undisturbed into the furnace, the author deems it advisable to give a further description of the stoker in question in the light of what is required today in the economical burning of coal for the generation of steam, touching particularly on those features that have been conspicuously faulty in chain grates. The following outline presents the entire situation at a glance, and later in the paper each of the items therein is briefly touched upon.

It is of interest to note that the difficulties with chain grates on eastern coal have been violations of the essential requirements of the modern stoker, so it is not surprising that the opinion prevails that success cannot be obtained with eastern coals using the conveyor-feed.

An adequate treatment of the first-mentioned stoker requirement in the foregoing outline would entail a discussion of what takes place in the fuel bed and would involve a consideration of the various types and feeds of stokers, but as such a discussion is outside the purpose of this paper this requirement will be discussed only as to the essentials upon which everyone will readily agree.

Present-Day Requirements of an Automatic Stoker Compared With the Performance of Chain-grate and Conveyor-Feed Stokers, Each Using Eastern Coals.

	Requirements of the Present-Day Stoker.	Results Obtained with Eastern Coals. With Chain Grates	Results Obtained with Eastern Coals. With Conveyor-Feed Stoker Described
1	It should completely burn all combustible that arises from the grate, and perform this task under the great handicap of using no more air than is required.	Thin fires spotted with upstanding coke result in excess air and low CO_2 due to the fact that the air supply is not graduated down to a minimum at the rear of the stoker and to influence attending the coking of the fuel bed	Graduation of air supply and thickening of fire near point of ash discharge and the prevention of coke assure a consistent 10 to 12 per cent. CO_2 content with positive assurance of an intimate mixture of air with combustible gas.
2	It should bring about low combustible in the ash.	Combustible in the ash from 30 to 50 per cent.	Combustible in the ash from 16 to 24 per cent.
3	It should burn coal at high rates of burning — not only to obtain high capacities but to widen the range of economical rates of burning as well, in order that great flexibility may be assured.	Rates of burning from 25 to 35 lb. of coal per sq. ft. of grate surface per hour.	Rates of burning up to 60 lb. of coal per sq. ft. of grate surface per hour.
4	It should be as nearly wholly automatic in operation as possible.	Successful in the matter of automatic operation.	Successful in the matter of automatic operation.
5	It should not entail unreasonable expense in the upkeep of the grate surface or of the furnace brickwork.	No unusual maintenance cost for furnace brickwork, but a very high one for grate links.	Use of mechanical draft imposes a more severe condition for furnace brickwork requiring a higher grade of refractories, but maintenance of ironwork is not excessive—in fact, may be considered quite satisfactory.

Air Distribution

Rather exhaustive surveys of the gas composition in various parts of the furnace were made frequently during the development work. These surveys showed that the zone of destructive distillation yields far greater quantities of combustible particles than does that well-spent portion of the fuel bed near the bridge wall. It follows, then, that air distribution must be regulated to supply large quantities of air to the coal during the early stages of combustion and limited quantities as the fuel nears the place of ash discharge.

It will be generally admitted that in order to burn completely all the fuel with a minimum of air it is of prime importance to provide each particle of combustible with its own quota of oxygen-giving air just as it rises from the fuel bed. The tuyere construction is well suited to such a requirement and lends itself admirably to these experiments. The tuyeres are cast in interchangeable sections containing varying percentages of air openings. This feature permits any desired gradation in air spaces to be made, between the two extremes noted in the tabulation below.

It is important at this point to recognize that the wind-box pressure is uniform under the entire grate. This provides high draft intensity and high air jet velocity for all parts of the fuel bed.

Low Combustible in the Refuse

The reduction of the combustible in the refuse to a satisfactory figure was brought about by taking advantage of the four following factors that have a vital influence on the character of the refuse: (1) Strong ignition; (2) A free-burning fuel bed; (3) Thickened fuel bed near the discharge end of the stoker; (4) High draft intensity through the nearly spent fuel.

The strong ignition temperatures have been referred to previously. On the conveyor-feed type of stoker, the coal burns from the top downward during the early stages, and from the bottom upward during the remainder of its travel. The higher the ignition temperatures, the quicker this reversal is established. An early burning from the bottom upward is recognized even in chain-grate practice, as being most effective in bringing about low combustible content of the refuse.

In a caked fuel bed of eastern coal, the air breaks through only at the fissures or cracks. Naturally the burning starts only at these fissures, and as it continues, holes are formed in the fuel bed. As the holes increase in size, the rate of burning decreases, due not only to the cooling ef-

Table 1—Air-space Distribution Adopted for Conveyor-feed Stoker.

8 per cent of 60 per cent.	= 4.8 per cent.	8 per cent of 60 per cent.	= 4.8 per cent.
22 per cent. of 40 per cent.	= 8.8 per cent.	2 per cent. of 40 per cent.	= 0.8 per cent.
Total air space	=13.6 per cent.	Total air space	= 5.6 per cent.

Conveyor elements, about 60 per cent. of total grate surface.
Tuyere elements, about 40 per cent. of total grate surface.

fect of large columns of cold air but also to the lessening intensity of draft occasioned by the increase in the effective air openings. This action results in a fuel bed characterized, in the final stages, by isolated lumps of coke surrounded by patches of bare grate. To prevent exceedingly low CO_2 the operator must run these bare patches out of the furnace and consequently dump the intervening or accompanying coke lumps into the ashpit.

With coking prevented and with each individual particle of coal preserving its identity, the air filters upward evenly throughout every part of the fuel bed. Freed from localized burning the fire now appears soft, intense and highly luminous.

The thickened fuel bed near the discharge end is brought about by the retarding mechanism described. (See Fig. 2.) When elevated the short pivoted bars C raise the nearly spent fuel above the chains, thus holding it back, and when depressed permit the conveyor elements to carry the ash out of the furnace. The relative duration of these two influences can be controlled by the operator and the fuel bed near the discharge end of the furnace can be held back and thickened to any desired depth.

The high draft intensity in connection with this thicker fuel bed has already been mentioned under the paragraph on air supply. Full wind-box pressure at this part of the grate forces high velocity air jets into the thickened bed and hence is particularly advantageous in burning out the remaining particles of combustible.

High Rates of Burning

From the foregoing references to mechanical draft it is quite apparent that high rates of burning are attainable with this new type of stoker. The replacement of the typical plastic fuel bed with the free-burning, intensely active bed obtained with the new equipment, materially assists in securing higher rates of coal consumption. High CO_2 results quite naturally from (a) the proper air distribution described; (b) the thicker fuel bed particularly at the discharge end; (c) the higher fuel bed temperatures that cause increased chemical activity; and (d) the impinging jet action on the fuel particles produced by small air spaces and forced draft.

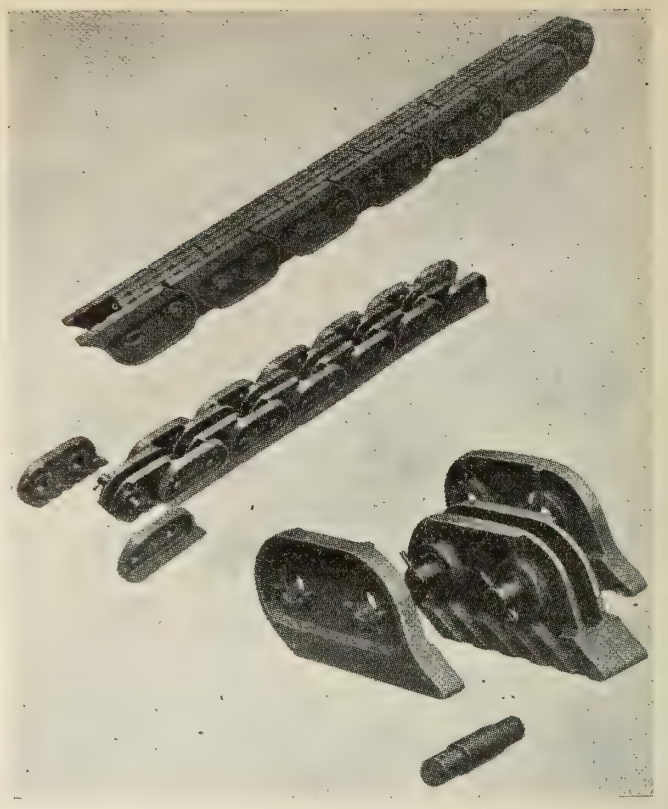

FIG. 4—DETAILS OF THE CONVEYING ELEMENTS MARKED "A" IN FIG. 2.

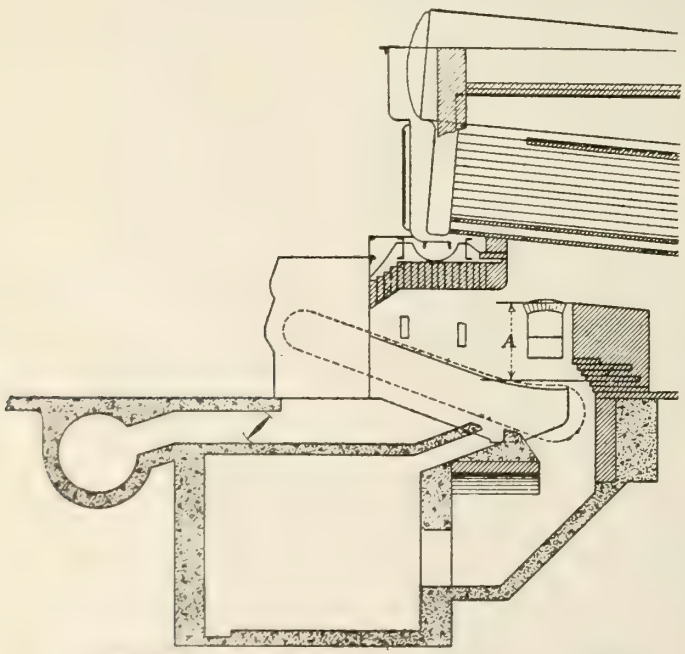

FIG. 5—SECTIONAL ELEVATION OF BOILER AND STOKER.
(Boiler has 2,500 sq. ft. heating surface and stoker 40 sq. ft., ratio 62½ to 1.)

Automatic Operation

In the matter of automatic operation it is only necessary to recall the basic principle of the conveyor-feed stoker — a positive feed fuel coal hopper to ashpit. The only action that interferes with this automatic and continuous performance and requires more than a minimum of attention from the operator is the formation of clinker on the side walls. This clinker accumulation is no more serious than with chain grates but experiments are under way to still further minimize the evil.

Eastern coals require less side-wall slicing than do those from the Middle West, probably because of the lower ash content with its higher fusing point. Also such coals have higher heat value and hence greater firing stability than Illinois coals. Because of these two advantages, the firemen of the experimental plant prefer eastern coals to those from the Central West when burned on the new stoker.

Low Maintenance

The thin uneven fuel bed at the discharge end of a chain grate combined with the low ash of eastern coals exposes the grates to the heat of the furnace. Moreover, with caking coals and chain grates, the procedure of partially closing the damper to raise the CO_2 content of the gases is too often resorted to, and such a practice invariably results in over-heated grate links.

The stoker herein described, by employing a deeper fuel bed and a thick layer of refuse near the bridge wall, effectively protects the grate from the heat of the furnace. In addition, full advantage has been taken of the cooling action of the incoming air. The small air spaces and the employment of mechanical draft produce high air velocities and this makes for cool links. An excellent idea of the very different character of the new link for eastern

coal and forced draft is obtained from Fig. 4.

High rates of burning and high furnace temperatures of course subject the furnace brickwork to very severe service. However, the wind-box pressures are low (less than 2-in. water column) and this, combined with the large number of uniformly distributed miniature air openings, causes the impinging flame or blow pipe action to disappear quite near the surface of the fuel bed, thus minimizing to some degree the brickwork deterioration.

The problem of more severe furnace conditions has thus far been met by employing refractories of a higher grade. The side walls and bridge wall have been made with standard 9-in. shapes and the writer is advised that the higher refractoriness of the brick used is in part due to its higher percentage of alumina and its low content of fluxes. Regarding the ignition arch, both the process and the mixture are new in stoker work. The material is highly refractory and porous and its performance under the harder usage bids fair to rival the ordinary arch maintenance in chain grates.

The essential points of this paper have been sufficiently marked to require no summary, but it may be said in closing that those connected with the experimental plant have derived considerable satisfaction in attaining the degree of success noted through the employment of such simple means.

COLOR SCHEMES FOR PLANT PIPING

By H. L. Wilkinson

The importance of some definite and unmistakable means of readily distinguishing between the various pipe and conduit lines and systems in the power plant has long been recognized by both designing and operating engineers. Particularly in large power plants is this question of vital importance, and it should be stated that in some of the well-ordered large power plants reasonably satisfactory systems have been installed. Also there has been some effort made to standardize this practice, a committee appointed by the American Society of Mechanical Engineers to investigate the question having reported upon the preferable distinguishing colours for the various divisions of piping systems in the usual power plant, so states the author at a recent meeting of the American Society of Heating and Ventilating Engineers.

While the importance of standardization in this detail of our power plants has been recognized, too little attention has been given to the matter of late, and the writer believes that its importance should not be overlooked. It is, therefore, suggested that the members of this society consider the following plan which is designed to apply to all piping systems.

It will be noted that the recommendation involves, in addition to piping lines, colour schemes for machinery, motors, hand-rails, dadoes, waste pails, elevator cages, etc., thus extending the usefulness of this distinguishing system to all parts of the industrial plant. It has been a revelation to the writer to find the cordial reception which this proposed colour scheme has received in many industries and concerns of national prominence, and the result is that new industries and concerns are taking it up continually. The application of this standardization might well be extended to the designating by distinguishing colours the tools used in various departments of a plant. This would bring about several benefits. In the first place, it would enable managers to hold each department of a plant responsible for its own tools. Then, because of the improved appearance of the tools, it would create more interest in their care on the part of mechanics. Last, but not least, it would surely be an insurance against tools being carried out of factories.

While the scheme designates definite colours for certain pipes, it is, of course, unnecessary to apply any one particular colour on any one pipe, the arrangement being flexible, so that an engineer may determine for himself his own design. In some cases, where there are as many as fifteen to twenty-five various pipe lines, it is necessary to use combination colours on some pipes, painting the straight pipe one colour and the joints, valves, elbows, etc., the alternating colour. Of course, some exceptions to personal selection will be found where an established custom has been in effect for some time, as in the case of sprinkler-pipes and all fire lines, where vermilion is the logical colour.

The advantage of this standardization will become readily apparent from the case of a certain plant where there was a stoppage or break in one of the pipe lines. The workmen carefully followed the line to the side wall where the trouble apparently existed, and opened up the wall for a considerable area, only to be confronted with everything but the line they sought. Of course the expense of ripping out the wall was nothing compared to the inconvenience and loss sustained, due to the suspension of operation until this repair was made. If this pipe line had been printed with a distinguishing colour and a small arrow placed on the wall where the pipe entered, indicating the direction the pipe took after enering the wall, all this difficulty would have been obviated.

NON-DESTRUCTIVE METHOD OF BELT JOINING

An unusual problem in the handling of hot cement clinkers with a temperature of 200° and over, was recently solved at the plant of the Standard Portland Cement Company, Leeds, Ala., in an interesting and cost-reducing manner. The method decided upon for moving the clinker was a rubber conveyor belt, but the clinker could not be cooled sufficiently in the process previous to conveying, to prevent scorching of the belt and its rapid destruction. The answer to this problem was found by running the belt at an incline of 12 degrees, so that the lower pulley dipped into a trough of water, thus carrying a film of cold water upon the belt, on to which the hot clinker from the loading hopper was deposited.

At this point a new problem was encountered; namely, how to join the belt so that the belt's full strength would be retained, and in a way which would withstand the extremes of temperature, the wear on the pulleys and the abrasion of the clinker. For this purpose Crescent belt fasteners were adopted, because they brought the belt ends tightly together in a snug joint, which made the belt practically endless on the pulley side, so there was no opportunity for clinker ash to get into the joint and abrade the belt ends, and also because in this method of joining, no metal came in contact with the pulleys to cause wear, and a permanent joint was thus assured. Moreover, the exceptional strength of the heads of the rivets and the formation plates prevented destruction of belt joint through abrasion by the clinker.

In six months of operation, this conveyor has carried 61,000 tons of clinker, and the Standard Portland Cement Company credits the saving of $300.00 in belt cost alone to this conveyor. The belt used was Goodyear Hy-temp, which is made particularly to withstand temperatures up to 200°, and is adapted for work on conveying jobs in mines, coking plants and cement factories where heat resistance and ability to withstand hard wear are prime requisites.

One of the most conspicuous forms of British engineering activity since the war lies in the growth of locomotive production. Every country in the world wants locomotives, and the extension of many locomotive shops in both England and Scotland, is designed to ensure that the demand will, as in the past, be met.

It is so far to the good that most of these shops were retained on locomotive work during the war. One firm alone supplied 152 locomotives to British railways, 380 to the French railways, and 300 for other overseas countries during the war. This was in addition to producing many narrow gauge locomotives, hundreds of "Tanks" and hundreds of thousands of shells, numerous aeroplanes, torpedo-tubes, gun carriages, and other "munitions." The total value of the company's output during the war was sixteen million pounds.

The Kelly Foundry and Machine Co., of Goshen, Indiana, have issued their catalogue G dealing with rocking, dumping, and stationary grates. The catalogue is well illustrated, and shows, besides the various types of movable grates, some portable kiln grates, stationary fire bars, and boiler front castings.

Common Sense in Engineering

A Lecture Delivered During the J. E. Aldred Lectures on Engineering Practice at John Hopkins University.

By WALTER M. McFARLAND

(Continued from last issue)

A very important feature in your engineering education and experience is to discover in any specific case the general principle which is involved and which may often be utilized to advantage elsewhere with considerable differences of detail from the original case. A circumstance of this kind came under my observation which illustrates the point quite well.

It was customary in the engines of the Navy up to about the beginning of the so-called "new navy" to make the eccentric straps of brass. Somewhat earlier than this, when steel castings had become available, designers for engines of the merchant service had made eccentric straps of steel castings lined with white metal, the idea being, of course, that the white metal furnished the suitable bearing surface, while the steel casting gave adequate strength. The steam launch on one of our vessels had the eccentric straps made of brass, as usual, half an inch square in cross section, and one of them broke. It was the lower half, which was a half circle with lugs to bolt to the other part. The young engineer who was charged with the repairs did not know of this practice in the merchant service, and having always seen eccentric straps made of brass, tried to make a temporary repair by taking a couple of sheets of one-quarter inch sheet brass, bending them to shape, riveting them together with a few copper rivets and bending over the ends to make lugs for attachment to the other part of the strap. Unfortunately, sheet brass is rather brittle, and, as might have been expected, this temporary strap broke off where the lug had been bent. After trying this a couple of times he was about to give up the attempt at repair and have a new strap made at a shop on shore. Another young engineer on board knew of the practice in the merchant service. It was out of question, of course, to get a steel casting, and it would have been difficult to arange for using white metal, but he remembered the principle of a proper bearing metal to go against the eccentric, backed up by a stronger one to stand the stress. Accordingly he took a piece of half-inch square bar iron, had it bent to shape and faced it with one of the strips of one-quarter-inch sheet brass, securing it to the wrought-iron backing with the copper rivets. This was properly fitted to secure a good bearing, and, of course, worked with entire satisfaction. Later on a new brass strap was secured for use, if necessary, but the repair was so satisfactory that the new strap was never used.

From the circumstances existing in educational establishments it is practically a mater of necessity that in solving problems the data should be furnished you and your work should be chiefly the handling of these data. When you get out into actual practice an exceedingly important part of your work will be the securing of these data accurately, which means that the observations must be made with care and with the aim to be thoroughly correct and reliable. It is not always possible to devise simple checks on the observations which will tell at once whether the records are reasonably accurate, but there are many cases where such checks do exist, and you should endeavor, if possible, to ascertain what such checks are. Some will come from previous observations and experience, some from study, but a great many will be a matter of common sense. A striking case which came under my observation and where common sense was the check is worth telling.

Most of the Mediterranean ports are protected by breakwaters so that the water inside is smooth, and as a result when coal is brought off to vessels it is in rectangular piles on flat scows. Unfortunately, coal dealers in the Mediterranean have a rather bad reputation for trickery. Consequently, in naval vessels when coal is taken on board great care is used in measuring the coal piles so as to be sure of the amount received. I was attached to a vessel which called in the harbor of Algiers. A couple of our midshipmen were detailer to measure the coal piles which were, roughly, 40 feet long, 20 feet wide, and between 5 and 6 feet high. At the end of the first day they handed in figures to show the amount received, which came to 375 tons. The executive oicer of the vessel had been attached to her for some two years, and so was familiar with the rate at which coal could be taken in. He said at once that some serious mistake had been made for the reason that never before had more than 300 tons been received in one day, even when the conditions were better for rapidity than existed at Algiers.

The midshipmen were told to go over their work again to see if there was any mistake, and they examined their computations but could find no error. I was the possessor of a slide rule, and was, therefore, supposed to be something of an expert on figures, and was called in to see if I could find what was wrong. I had had nothing to do with the coaling, but was on board during the day, and happened on several occasions to notice the young men while they were making their measurements. I checked up some of their arithmetical work and found it was correct, so it seemed that the trouble must be in the measurements themselves. I remembered that when I saw them making the measurements the particular piles on which they were working did not come above their heads, while I noticed a great many heights recorded as being over six feet. The solution of the difficulty then occurred to me at once. They had used one of the tape measures from the engine room. If you do not know it now you will learn by experience that the ordinary linen tape measures are fitted with a brass ring in the end for convenience and to prevent the tape from slipping into the case. These rings are invariably torn off after a relatively short service, and the common practice is then to tie a knot in the end of the tape and to make all measurements from the 1 foot mark. I asked the midshipmen if they had used the linen tape, and found they had. It appeared on further investigation that the man who held the knot recorded the figures, which were caled off by the man at the other end. The recorder assumed that the other man had deducted one foot before calling off the measurement, while the man at the other end called off what he saw, assuming that the recorder would deduct one foot. There would have been no easy way to check this on the measurements of 20 feet and 40 feet, but obviously it was absurd to put down heights of 6 feet 3 inches and 6 feet 6 inches when, as a matter of fact, they were looking over the piles. Remembering that when I saw them the piles were below the tops of their heads, I asked them if there were any piles which they could not look over. On reflection they said that there were none. I asked then where they got their heights of over 6 feet, and at once the error developed that every measurement they had made was one foot too great. When the correction was made the amount of coal received was only 275 tons instead of 375.

As you hear the story you may think that these young men were unusually stupid. As a matter of fact, this is not true at all, and both have since made enviable records in the navy. They simply failed to use common sense in applying the obvious check as to height when they could look over the piles of coal, which should have at once have called their attention to the carelessness with which they were making the measurements.

While speaking of this subject of checks on observations you will in time

acquire a great many of these from practice and experience, and it is well to do so as soon as possible. For example, with good average coal of, say, 14,500 B.t.u.'s pepr pound, if all the heat went into the formation of steam (that is 100 per cent. efficiency) you would have evaporation from and at 212° F. of about 15 pounds. Likewise, with good quality fuel oil of, say, 19,500 B.t.u.'s the corresponding evaporation would be about 20 pounds. These are figures easy to remember, and when you remember in addition that the best average results in good boilers are about 75 per cent. efficiency with coal and from 80 to 82 per cent. efficiency with oil, you will be in a position to discourage fairy tales about remarkable performances in the way of boiler efficiency. It is the custom now in all carefully-conducted boiler tests to tabulate what is known as a "heat balance," showing the way in which the heat in the fuel is distributed. Two elements of loss which are present in every fuel are the heat carried away in the dry chimney gases and the loss due to moisture formed by the burning of hydrogen. The sum of these two losses at moderate rates of combustion is, roughly, about 15 per cent. in the case of coal, and about 14 per cent. with oil fuel. You will see at once that if all the other losses are eliminated the possible efficiencies would be only roughly some 85 per cent. Consequently, if figures are shown you indicating an evaporation of 13 or 14 pounds of water per pound of coal, or 18 or 19 pounds of water per pound of oil, you will know at once that these results are impossible. Either there has been excessive priming of the boiler or there has been an error in the observation of the amounts of fuel and water.

Some years ago a friend of mine who is a very able engineer was discussing the matter of what is known as "surface combustion," where the gassified fuel passes through a porous earthen plate and burns on the surface. He asked if I had gone into the matter carefully, and I told him that while I had read something about it, I did not know very much. He then went on to say that it was a matter of the very greatest importance because the efficiency with this method of combustion was claimed to be five or six times as great as by any other method. I reminded him at once that this was absurd because a good average performance with oil fuel gave 80 per cent. efficiency, and five times this would have been 400 per cent., which was, of course, ridiculous. He then concluded that the ratio of five or six times referred to the efficiency of an open grate or some other similar very inefficient method of burning coal.

While as engineers we always want our work to be accurate, common sense teaches us that there is a time for everything, and there are often occasions where you want to reach a decision quickly and where approximate data will be just as useful as those which are absolutely accurate. You will find as you go along that there are a number of "thumb rules" or "round figures" which are very convenient to carry in your memory for just such occasions. For example, a square foot of sheet steel one inch thick weighs approximately forty pounds, which gives you a "round figure" easy to remember and easy to divide for sizes which you are likely to need. The error is only about 2 per cent. Again, one foot in length of a tube four inches in diameter gives one square foot of surface, and two feet long of two inches diameter, and four feet long of one inch diameter. Here the error is a little greater, being about 4 per cent.

There is another convenient figure to remember at the present time—when the question often comes up as to whether it will pay to change a coal-burning installation to one using oil. If you will take the relative thermal values of oil and coal and allow for the higher efficiency when using oil than coal, which is, roughly, about 10 per cent. of the efficiency with coal, you will find that the cost for the same thermal value of fuel may be expressed as follows:

When the price of oil in cents per gallon is half the price of coal in dollars per ton (of 2,240 pounds) the cost for the fuel only is the same. In other words, two-cent oil costs the same as $4 coal. There are economies in using oil due to a smaller boiler-room staff, the absence of ashes and other things, which must be considered, but this "thumb rule" will often enable you to say whether the step is worth considering at all. For example, if oil is selling at five cents a gallon while coal can be obtained for $5 a ton, it is perfectly evident that the difference in the cost of the fuels is so great as to make it unwise to change. If, however, oil, say, is four cents a gallon and coal $7 a ton, the difference is then so small that it is possible the other savings would justify shifting over to oil, so that it is advisable to make a detailed investigation.

From one point of view the talk that I have given you may be regarded as rather disconnected, because so many subjects have been considered, and yet the same theme runs through them all —the application of common sense in the solution of engineering problems. Perhaps the very diversity of the subjects may impress you all the more with the great importance of common sense.

My aim has been to encourage you to develop and trust your own common sense by showing how it applies everywhere and is of the greatest service. Indeed, without it great mental ability is often helpless or goes wrong. One of the most brilliant engineers whom I know, who has designed some of our most important electrical machinery, and who is an accomplished scientist, once said "nine-tenths of good engineering is common sense." And, in closing, let me say again that common sense is not a special gift and does not replace careful study, but it does mean the application to the problem at hand of your best experience and judgment without prepossession or prejudice.

COPPER-ALUMINUM-IRON BRONZE AS AN ACID-RESISTING ALLOY

By O. L. Kowalke

Copper-aluminum-iron bronze is known to possess many valuable qualities. In tensile strength it ranks with mild steel. It can be forged while hot, and also rolled into sheets; it can be machined to a nice finish, and sound castings can be made of it, free from shrinkage-holes and blowholes. These among other qualities render the alloy suitable for bearings and gear. But very little has hitherto been known concerning its acid-resisting properties. With a view to acquire knowledge in that direction, a systematic series of tests have been made at the University of Wisconsin laboratories. The results of these tests, which were made with various acids and alkalies, are set out for detailed comparison in three tables. Only two of the bronzes experimented with are reported on; they are distinguished as A and B. Their average compositions and properties were:

	Bronze A	Bronze B
Copper	87.0 %	85.6 %
Aluminium	9.8 %	10.81%
Iron alloy	3.11%	3.57%
Ultimate unit stress	74,800 lb. sq in.	66,600 lb. sq. in.
Reduction in area	19.0 %	13.0 %
Elongation in 2 in.	21.0 %	11.5 %
Specific gravity	7.71%	7.58%

The specimens for the corrosion tests were approximately 1 in. by 0.07 in., and were finished smooth, with square edges. Most of the tests were made at room-temperatures of 72 deg. F. and 85 deg. F., but a few were made at 194 deg. F.

Bronze A was found to be resistant to several acids, particularly to sulphuric, lactic, phosphoric, tartaric, and acetic acids. Nitric acid attacked the metal readily, the concentrated acid acting violently. Hydrochloric acid and ammonia solution both attacked the metal too readily for commercial purposes. Caustic soda had but little effect. In the case of bronze B, a strikingly higher resistance to sulphuric acid is shown. Also ammonia did not corrode it so readily as bronze A. Nitric acid attacked bronze B also too readily; and hydrochloric acid attacked it more readily than bronze A. It is interesting to note that the corrosion, in 35 per cent. sulphuric acid, of a forged specimen of bronze A is only about half that of the rolled-sheet and cast forms.

The Illinois Stoker Company, of Alton, Ill., have issued a catalogue "L," describing their natural and forced draught type of mechanical stokers. These are of the chain-grate type, those for natural draught being type A, and the force draught, type G. A preface is included, showing the advantages of mechanical over hand firing, and following this is a well-illustrated section descriptive of the two types. At the back of the book is a description of the Illinois arch, and a chapter on boiler and furnace efficiency, including several diagrams.

Some Useful Information on Gauge Glasses

The Various Troubles to Which They Are Subject Are Discussed Also Means of Preventing Some of Them—The Right and Wrong Way of Fitting a Glass is Explained

By H. E. WAVERLEY

THE glass water gauge, which is such a familiar object and may be seen on almost every boiler front, may be considered a time and labor-saving device, and to a certain extent a safety appliance also. The glass gauge, like other safety appliances, must be kept clean and in good condition at all times in order to ensure reliable indications of the water level in the boiler. It is a simple device to keep in order, and not a difficult one to repair when it gets out of order. Where raw feed-water is employed, as is generally the case where boilers are not used for power purposes in non-condensing plants, the gauge glass should be kept clean by blowing out at regular intervals. The interval between cleaning-out times depends upon the quantity and the quality of the water used. Muddy water deposits a sediment, principally mud, while clear water deposits carbonate and sulphate of lime and magnesia which form scale.

When closing the valve after blowing out the column and glass, a certain quantity of water carrying deposits is retained in the column and glass, and in a few minutes these settle along the bottom of the lower column pipe and in the bottom connection leading to the glass. If the blow-off valve be now opened a very little and for about 5 seconds these accumulations may be removed before they have had an opportunity of becoming attached to the surfaces, and without renewing the entire contents of the column and glass. By a careful manipulation of the blow-off valve under the water column, and of the drip-cock under the glass, these parts may not only be cleaned of sediment but they can to a considerable extent be kept free of such troublesome accumulations. Where the feed-water is very bad and the amount of sediment is found to be large, it always pays to be very careful when blowing out the column and glass, and to remove as much of the deposits as possible, not because of the trouble that would otherwise be experienced in removing hard scale, but to ensure accurate indications of the water level at all times and upon which the safety of the plant very largely depends. The glass water gauge in many plants is relied upon almost entirely from one week's end to the other, the gauge cocks being used in emergencies only. It is nothing more or less than criminal negligence to place so much confidence in a glass water gauge unless great care is taken to ensure its proper condition at all times, and that can only be done by frequent and thorough cleaning.

In certain works on steam engines and boilers directions are given for the proper care of the water column and gauge glass. The directions are generally to the effect that the glass should be blown out from four to six times each day, and that the gauge cocks should be tried at least once every half-hour. These directions are decidedly on the safe side in one respect, and that is that a gauge-cock cannot possibly clog or become scaled over during a single half-hour, and with the worst possible feed-water and condition of boiler. On the other hand, experience with different firemen and water tenders seems to indicate that the directions if followed to the letter eventually lead to dangerous conditions.

It must be understood that there are exceptionally careful men to be found in boiler-rooms, and there are water columns fitted with exceptionally good gauge-cocks and water gauge connections. The directions referred to are all that can be desired when these exceptional conditions exist, but under ordinary conditions the very frequent use of these important devices produces needless wear and a large amount of avoidable labor and annoyance. Gauge-cocks cannot be expected to remain steam and water-tight for many weeks when used twice an hour day after day, and when they begin to leak at very short intervals and spatter mud and water over a nicely kept boiler front the temptation to plug them, or to repair them and then neglect to use them often enough to ensure safety, is indeed very great, and too often proves irresistible. The moderate use of gauge-cocks is all that is necessary to ensure safety, and it further ensures the continued use of the gauge-cocks without leakage or other inconvenience.

Gauge glasses as a general thing break oftener when frequently blown out. There is a practical limit to the frequency with which the glasses should be blown out the same as with the opening of gauge cocks, and the limit depends upon the frequency with which the boiler is cleaned, the kind of water used, and the kind of glass gauge fittings employed. With fittings having liberally proportioned openings leading to the glass, say, not less than ¼ inch in diameter, and when the boiler is cleaned every two weeks or after 135 hours' run, four times a day is often enough to blow out the glass, and three times a day is often enough for the water column. A day is assumed to be the length of time necessary to prepare for a day's run of ten hours, and to prepare the machinery for the night after shutting down.

Glasses last anywhere from two minutes to two years on power boilers, and frequently as long as three years on boilers used for low pressure heating. Probably three or four months would be a fair average for power boilers carrying pressure of 100 pound and upward. Glasses used on power boilers are generally blown out much oftener than the glasses on heating boilers, especially in non-condensing plants. The effect upon the glass of frequent blowing, and consequently of frequent heating and cooling, is similar to what is known as the fatigue of metals. After expanding and contracting rapidly a certain number of times the glass will fail. If such a glass lasts 24 hours it will generally last a month or more. When the packing, which is soft and pliable at first, becomes dried out and hard as it will in the course of a month or two, the glass is more apt to break because it is not as free to expand as it was when the packing was first put in, and this, together with the alternate heating and cooling and the gradual wearing away due to blowing out the glass, tends to greatly shorten the life of gauge glasses when used on boilers supplying high-pressure steam.

When condensed steam is fed into the boiler, or gravitates into it from the heating system, very little deposit and accumulation of scale occurs, and the water is generally clear and of course does not tend to obstruct small passages quickly, so that the gauge cocks are seldom used, and the gauge glass is blown out at rather long intervals. Glasses last much longer under the latter conditions.

The gauge cocks should be used to check the indications of the glass each time the latter is blown out. It is important to have the fittings exactly in line with each other, and to have them large enough so as not to cause the glass to bind or to be cramped in the least. When the fittings are not in line the glass is apt to be cramped either when putting it into the sockets in the fittings or when tightening the packing nuts. When tightening the nuts around a glass when in the position indicated in Fig. 1, the tendency is to straighten the glass—that is, to bring the glass into a position parallel to the socket at the end being tightened, and this tends to bend the glass, as shown in Fig. 2. It is, of course, impossible to bend the glass consequently the glass either snaps when the nut is turned or when the glass expands when it becomes heated. Failure to notice these little points is responsible in many cases for continued annoyance from breaking gauge glasses.

Sometimes it is necessary to ream out the fitting, say 1-32-in. or 1-16-in. larger so as to give the glass sufficient free-

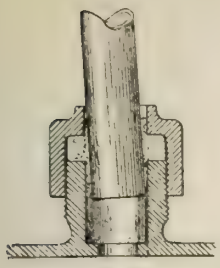

FIG. 1.

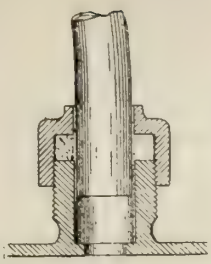

FIG. 2.

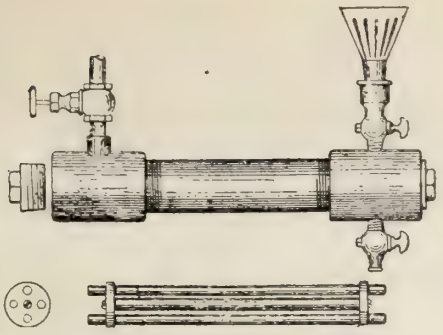

FIG. 3.

dom. Wrenches should almost never be used for tightening the packing nuts around the gauge glass. When a glass is packed with the proper kind of packing and the nuts have been screwed up just tight enough to prevent leakage when both the glass and the packing have been warmed, the glass may readily be turned around in the fittings with merely the thumb and forefinger.

After putting in a new glass turn on a very little steam, leaving the drip at the bottom of the glass open so that the steam will gradually fill the glass and escape through the drip cock. The glass is thus warmed thoroughly before the water is let into it and before it is subjected to pressure. When the glass has become thoroughly hot, open the steam valve wider, then open the water valve a like amount, and continuing to open both valves alike until fully open, then slowly close the drip at the bottom. This method not only allows the fittings to be thoroughly blown out, but enables the operator to increase the pressure on a new glass and new packing more gradually. The drip-cock should now be opened and closed suddenly. If the fittings are filled with sediment to such an extent that sudden opening and closing of the drip-cock is necessary to clear it, it is evident that the drip is not opened often enough, or that the boiler is extremely foul.

When the drip has been closed for some time the water in the glass will become comparatively cool which is due to the absence of circulation, while the upper part of the glass will become comparatively hot. As this change of temperature in the low end of the glass takes place very slowly, no trouble is experienced, but when the drip is opened suddenly and the steam is thus brought in contact with the cooler end of the glass the latter very frequently breaks, and when that is the cause of breakage the glass will nearly always fail at some point below the middle, and generally about one-third the length of the glass from the bottom.

It frequently happens that an entire package of gauge glasses will prove to be too hard and brittle, and that the entire number will break within a few minutes after putting them in. It is due to experiences of this kind that many engineers have been led to anneal all the glasses before using them. This is generally accomplished by means of a water and steam bath, the water and the glasses being heated by steam. Engineers generally rig up some apparatus with what old material they have on hand that will accomplish the purpose. A simple device that has given satisfaction for this purpose is illustrated in Fig. 3.

It consists of a short piece of 2-in. or 2½-in. pipe about 4-in. longer than the glasses. On one end is screwed a coupling with the outer end plugged, and a drip-cock screwed into the upper and lower sides. On the other end is a reducing tee, which is plugged at the outer end, and a ½-in. or ¾-in. pipe screwed into the smaller opening at the side. A valve is placed in the smaller pipe close to the tee. The vertical pipe is connected to the boiler or to one of the steam pipes. A rack made of wood is provided having suitable holes in both heads for the gauge glasses; the rack serving to keep the glasses away from the pipes.

The plug is removed, as shown, and the rack containing the glasses slipped into the pipe. The plug is then screwed in and the pipe filled with water of the same temperature as the air in the room. Both cocks being closed, the valve is opened and the condensed steam in the vertical pipe, which is practically cold, is admitted into the remaining space in the 2-in. pipe and connections. The lower drip-cock is then opened a very little thus permitting the water and condensed steam to gradually work out, which admits steam and heats the pipe and the glasses very gradually. When steam issues from the lower cock the valve is opened wide, the cock serving to keep the pipe drained. The glasses are then kept under boiler pressure, and consequently at boiler temperature for from three to four hours. At the end of that time the lower cock is closed, when the pipe at once begins to fill with hot water, the water cooling down very gradually owing to lack of circulation as the vertical pipe becomes filled. When the pipe has cooled to its original temperature the valve is closed and the two cocks opened thus draining the pipe. The plug is then removed and the glasses taken out, dried, and put away again in the box.

Glasses treated in this way have given the best of satisfaction on high-pressure boilers where the change of temperature when blowing out is very great, and where glasses are subjected to draughts of cold air, and also for portable and hoisting engine boilers, which are subjected to rather severe usage, as far as changes of temperature are concerned. Any other device which will permit the glasses to be heated very gradually and again cooled very gradually will serve the purpose fully as well as the one just described.

The bursting of gauge glasses is attended with not a little personal danger and discomfort, and it is important that all reasonable precautions against such breakage be taken by the person in charge. When a gauge glass breaks when under pressure always close the lower valve first. It is cheaper in the long run to cut glasses with a gauge-glass cutter than to attempt to cut or break them off with a broken file, or by similar means, because a slight nick in the glass at the wrong place may mean the early destruction of the glass when subjected to pressure and varying temperature.

There are other practical means for preventing the breakage of gauge glasses. Some engineers fit a thin brass or copper thimble into the upper end of the tube, as shown in Fig. 4, which prevents scale and water from coming in contact with the glass when blowing out the latter, and hence it reduces the eroded and pitted appearance commonly seen at the upper end of unprotected glasses. Tubes made of aluminum may be obtained of dealers in engineers' supplies which accomplish the same result.

These tubes and thimbles, it will be seen, protect the inner surfaces of the glass only, and as the glass is liable to be crowded to one side or the other in the packing nut as well as in the fitting itself, it is a good plan to also protect the glass on the outside. A simple means of protecting the glass on the outside is also obtained from dealers in gauge glasses.

It consists of a rubber sleeve adapted to slide over the end of the glass, as shown in Fig. 5. The glass cannot come in contact with the socket in the fitting, neither can the packing nut touch the glass when the packing is screwed up. The combination of the thimble and the latter device prevents the rapid wear of the glass at the top, and also retains the glass clear of all metallic contacts which has been found to be very desirable where glasses are subjected to high pressure and temperature and sudden changes in the latter.

When the rubber protector is employed separate packing rings are not needed, because the packing forms a part of the sleeve as shown. Annealed gauge glasses protected inside and out by this or similar means will last as long under any circumstances as it is possible to make them by any means thus far made known.

Many engineers suffer unceasing annoyance due to breaking gauge glasses because they do not pack them with the proper material. Candle wicking and asbestos wicking should be used only in case of emergency. The latter materials are too porous and require too much

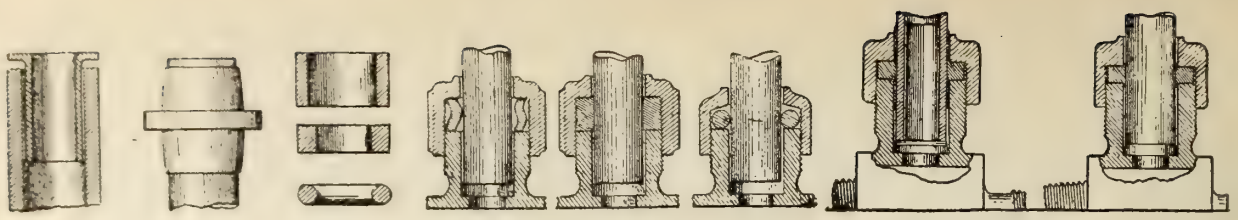

FIG. 4. FIG. 5. FIG. 6. FIG. 7. FIG. 8 FIG. 9. FIG. 10. FIG. 11.

pressure in order to make a tight joint to be suitable for packing a glass tube of any kind. The wicking soon becomes charred and hard and begins to leak, and it is evident that after it becomes hard it is useless to attempt to tighten the packing nuts. A second tightening merely serves to compress the glass so tightly as to prevent the necessary expansion, and the almost invariable result is breakage.

When a gauge glass is packed with wicking, either candle wicking or asbestos, and begins to leak at the end of, say, a month, the best thing to do is to repack the glass. Tightening the nuts on hard, dry packing, especially on an object so delicate as a gauge glass, avails nothing in the long run; but, on the other hand, it does add immensely to the number of glasses broken in a given time. Soft-rubber rings of the proper size are by far the best, and consequently these rings furnish the cheapest means of packing gauge glasses. The first cost of rubber is merely a trifle greater than that of wicking, while the life of the packing is more than doubled, and the number of glasses broken is greatly reduced.

Rubber rings are made in three forms or shapes when referring to cross-section —viz., the thimble, the square ring, and the round ring. These are shown in Fig. 6. Which of these three shapes will be found the more serviceable will depend upon how they fit the packing nut. Gauge-glass fittings are made of a variety of designs, some having a wide but shallow space to receive the packing, while others have a narrow and deep chamber between the sides of the nut and the glass. It is evident that the same form of packing cannot well be used equally well with all forms of packing nut. That is getting details down rather fine, but it is well worth considering when we remember that the durability of the glass and the safety of one's eyes depend largely upon the manner in which this work is done.

The packing ring should be of such size and shape that one ring only at each end of the glass will be required. A good job of packing gauge glasses can seldom be done when two or more rings are employed. When a rubber thimble is used on a packing nut adapted to the square ring, the result is about as shown in Fig. 7. This may be exaggerated a little, but it serves to illustrate the principle. The rubber thimble is particularly well adapted to the style of nut illustrated in Fig. 8, because the space between the nut and the glass is of the same shape, and is nearly the same size as the ring. The ring in this case is merely compressed lengthwise, and this becomes wider without any tendency to buckle or double up.

If fittings are used having a wider space for the packing, either the square or round rings give better satisfaction. The round ring is particularly well adapted to fittings having bevelled edges and nuts as shown in Fig. 9. The inclined surfaces are supposed to assist in crowding the packing against the glass, and perhaps they do, but as a general thing the bevel or angle is so slight that it is doubtful whether it is of much assistance in making a tight joint. When the edges of the fitting and nut are square, the square packing ring is best adapted, as shown in Fig. 10.

When two rings are employed the resut is very apt to be similar to that shown in Fig. 7, on account of the yielding nature of the rings, and this is especially so when both rings do not fit the nut perfectly, one ring tending to crowd the other away from or against the glass, thus rendering one of the rings practically useless, and the other one less efficient. A glass packed with a protector ring, and also protected on the inside is shown in Fig. 11. It will be seen that this is an ideal arrangement when the water is muddy and the glass and water column have to be blown out frequently.

There may be found on the market at a reasonable price rubber packings adapted to every construction for gauge glass fitting regularly made; also highly annealed glasses under various trade names, and after considering the subject as thoroughly as its importance demands it will readily be seen that in order to secure a tight joint with the least possible pressure, thus avoiding any tendency to break or to cramp the glass due to the packing, it is necessary to obtain a form of packing that will fit snugly in the space in the nut.

To get the best result from gauge glasses in any service first procure a good glass, then get suitable packing and keep it in a cool, dry place so that it will not harden. See that the fittings are in line, then pack the glass and screw up the nut with the fingers only. If the glasses break frequently, try some means for protecting them inside and out, and also anneal the glasses, which may be accomplished in the manner previously explained. A little more careful attention to the seemingly insignificant detail in a steam plant will be the means of saving a great deal of needless annoyance and not a little danger of personal injury.—"Southern Engineer."

A REMARKABLE RUBBER DISCOVERY

A discovery of the highest importance has been made by a lecturer in chemistry at the Manchester (England) School of Technology. When rubber and sulphur are mixed together at a high temperature the rubber becomes hard and tough—"vulcanized" is the technical term for the change. While rubber can stand the necessary heat, other raw material with which it might be usefully mixed would be destroyed. The new invention is a cold process, in which two gases are used to produce the free sulphur required in vulcanising. When crude rubber, either in the solid or the liquid form, is treated with the two gases it becomes efficiently vulcanized, and when it is mixed with any waste material such as sawdust, leather scraps, or paper, a similar change takes place without the properties of the waste material being affected. This discovery is to be applied immediately to the manufacture of linoleum, the heavier classes of wallpaper, and artificial leather for upholstery. It is also applicable to the manufacture of one-piece boots (of rubber and leather scrap) and of felt (combining rubber and "shoddy").

ANOTHER FIRM TO BUILD DIESELS

The Worthington Pump and Machinery Corporation have issued a bulletin announcing their entry into the marine Diesel engine construction field. The bulletin reviews the marine situation and the case for the Diesel internal combustion engine, and quotes instances of actual working to demonstrate the reliability of this prime mover. The announcement of the building of a 2,400 I.H.P. six cylinder marine Diesel by the company follows. This engine was built at the company's Snow Works, Buffalo, and the cylinders are 29 inches bore by 46 inches stroke, and the crank shaft makes 120 revolutions per minute, the engine being of the 4 cycle type. The engine is built to the Worthington Company's own designs, but the leading features of successful foreign builders have been incorporated. The company have made plans to enable them to produce these engines in large numbers as the demand increases.

The Theory and Practice of Electricity

In These Articles the Theory Will be Developed Sufficiently to Enable the Practical Man to Grasp the Underlying Principles of Apparatus Under His Care, Both Direct Current and Alternating

W. F. SUTHERLAND

MAGNETISM and electricity are so intimately related that one can hardly be studied without the other. In the earlier days of electrical science this relation was not so apparent and it has only been during the past century that the true relationship has been worked out. From the study of these things indeed the whole electrical industry of to-day is largely based.

In the last lesson it was seen that the lines of magnetic force around the poles of permanent magnets could be visualized by means of iron filings. If we now take a piece of cardboard and passing a heavy wire through it cause a current to flow through the wire; by sprinkling the cardboard with iron filings we shall see the filings arrange themselves in concentric circles around the wire, much as is shown in Fig. 22.

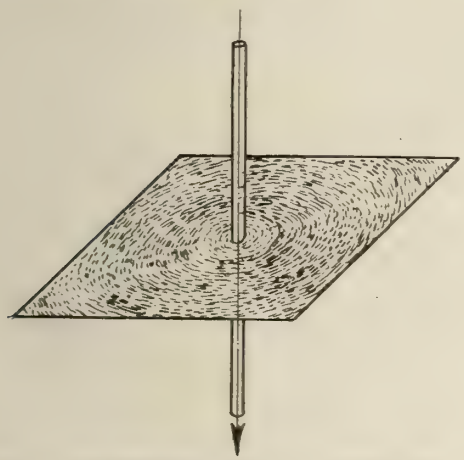

FIG. 22—MAGNETIC FIELD OF FORCE SURROUNDING A WIRE CARRYING CURRENT AS SHOWN BY IRON FILINGS.

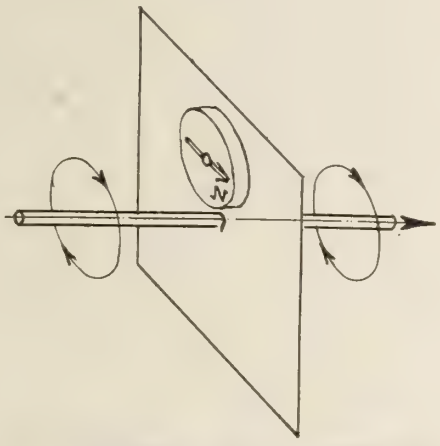

FIG. 23—MAGNETIC FIELD OF FORCE SURROUNDING A WIRE AND DIRECTION OF FLOW.

This will give rise to the suspicion in our minds that the electric current exerts some kind of force upon the field of space around the wire through which it is passing and from the behavior of the filings we will naturally conclude that some form of magnetic force is present. This is the case, although a difference exists between the magnetic fields of magnets and wires. In a permanent bar magnet the lines of force emerge at one end and enter at the other, while in a wire carrying current the lines of force surround the wire.

If instead of filings we use a compass as in Fig. 23 and move it around the wire on its cardboard support we will find that the needle changes its position and any point on it will trace a circle around the wire, the needle always pointing in a direction tangent to a circle drawn through its centre. Examination will show that the magnetic force gets bigger as the current increases, disappears when the current stops and reverses if the current is reversed.

Direction of the Magnetic Flux Due to Current

From the behavior of the needle when the current is reversed, it may be suspected that the direction of the current has quite an effect on the direction of the magnetic lines of force surrounding the wire. In Fig. 23 if the wire is carrying current in the direction indicated by the arrow at its lower end, then the needle will come to rest with the north pole pointing out at the observer. If the current is now reversed and made to flow up through the wire instead of down, the compass needle will immediately swing around and point with its north pole away from the observer. In the first case the lines of force are said to travel around the wire in the direction shown by the arrows on the two circles.

The direction which the lines of force will take may be easily remembered by thinking of a right hand nut and screw. If the nut is turned over to the right on the screw it will travel away from the observer. The direction of rotation of the nut corresponds to the direction of the magnetic lines of flux, while the travel of the nut along the screw indicates the direction of current flow.

The relations between current flow and magnetic flux are also easily remembered by another simple little rule shown in Fig. 24.

The right hand is supposed to grasp the wire with the thumb extended along it in the direction in which the current is flowing. The fingers of the hand will then wrap around the wire in the direction in which the magnetic flux is travelling.

The Solenoid

If we take a coil of wire and thread it through a piece of cardboard as shown in Fig. 25, then pass a current through it and sprinkle iron filings on the cardboard, a figure will be obtained much as is shown. The filings will arrange themselves in an orderly pattern. Some of them will group themselves in little circles around each individual wire, but the majority of them will group themselves in lines passing around all of the wires in through along the axis of the coil and around to the outside. It will be seen that the figure has some resemblance to that made by a permanent bar magnet and we have actually produced a magnet though perhaps weaker and of no consequence. If the current is interrupted the filings will lose their orderly arrangement and will show no indication of lines of force.

Magnetic poles are formed in the same way as with the permanent magnet, at the ends of the coils. The reason for this may be better understood from Fig. 26. Here a small coil is shown in section with the top part cut away. The current is travelling in the direction indicated by the arrows and the magnetic lines of force around each wire, indicated by the circles have the directions shown. In the top half of the diagram the flux will travel clockwise since the current is flowing away from the observer, while in the bottom half they will be seen to travel in the opposite or counter-clockwise direction since the current is flowing towards the observer. By applying the right hand rule given above this will be seen to be so. Instead of the magnetic flux, due to each wire passing around the individual wire, the greater portion of it will flow around all the wires and we will thus have a strong stream of magnetic flux passing through the coil emerging at one end and entering again at the other.

If a bar of iron is placed in the centre of the coil of wires shown in Fig. 25 the magnetic effect will be found to be very much increased. As stated in the last issue of Power House, some materials have the property of offering much less resistance to the flow of magnetic flux than others. Iron in some of its forms is one of the best conductors for magnetism and its insertion into the magnetic circuit lowers the magnetic resistance appreciably. Thus supposing we have the same coil and the same flow of current through it the force causing the flow of magnetic flux will be the same, but since the magnetic resistance,

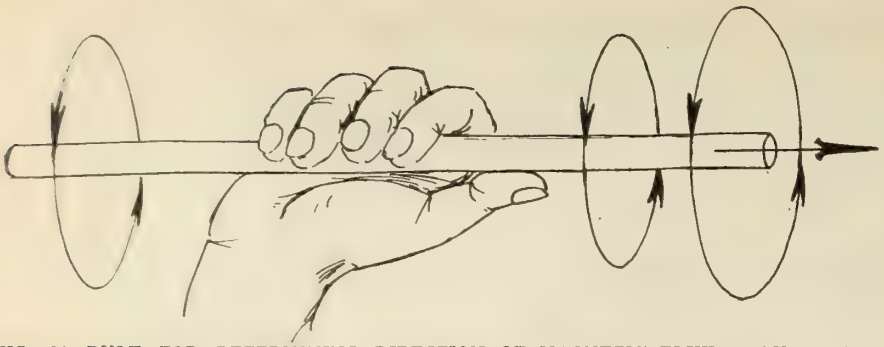

FIG. 24—RULE FOR DETERMINING DIRECTION OF MAGNETIC FLUX AROUND WIRE CARRYING CURRENT.

if it may be called such, will be much less, a greater effect will be produced.

There is a limit to the amount of magnetic flux which can be forced through iron or rather it becomes more and more difficult to increase the strength of any electro-magnet after a certain point is reached. In many problems it is important to be able to express the amount of flux as a numerical quantity and a unit has been chosen for this purpose called the Maxwell. This name that when magnetized to a high flux density the permeability or capacity for further magnetization greatly decreases. Under such conditions the magnetic material is said to be approaching saturation and with very high flux density is said to be saturated. Saturation is rather an indefinite term. With good wrought iron or steel it would be reached at something like 20,000 or more lines per sq. centimeter, while in cast iron it would be in the neighborhood of 8,000.

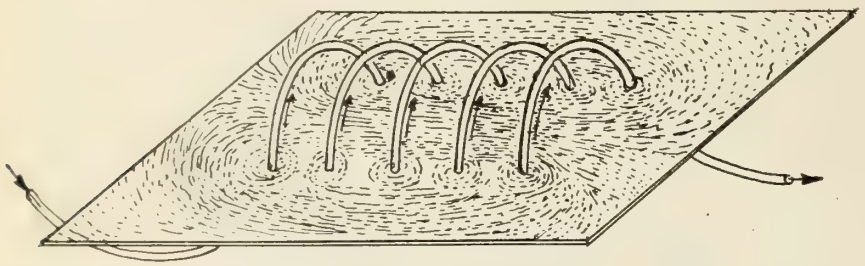

FIG. 25—THE MAGNETIC FIELD OF FORCE SURROUNDING A SOLENOID AS SHOWN BY IRON FILINGS.

is somewhat out of use at present and instead of saying so many Maxwells, it is more usual to say so many lines of force. The flux density or the strength of the magnetic field is measured in lines of force per square centimeter or per sq. inch. This unit finds considerable use in the design of electrical apparatus. Iron and all other substances which are magnetic have the peculiarity

In Fig. 24 a method of determining the direction of flow of magnetic flux around a wire carrying current was shown. Fig. 27 shows a corresponding method of determining the polarity of solenoids or electro-magnets. In this case the coil of wire is grasped by the *right* hand with the fingers pointing in the direction of current flow. The thumb extended along the coil will point in the direction of the magnetic flux and since the flux flows out of the north pole the thumb will also point towards the north pole of the magnet or solenoid.

In the next issue of Power House the elementary theory of dynamo-electric theory will be discussed.

Uehling Instrument Co., 71 Broadway, New York, has just issued Bulletin No. 111 describing style U Uehling CO_2 equipment. This is a new design built in single and multiple forms, the latter serving any number of steam boilers simultaneously, up to a total of six. The purpose of this equipment is to save fuel by burning it with the proper air supply. Neglect of this factor is costing power plant owners heavily. Among the notable features of the new machine are speedy action, resulting from a new form of aspirator, absence of chemical solutions, greater simplicity and the unique plan of providing an auxiliary boiler front CO_2 indicator, which guides the fireman, while the CO_2 recorder, installed in the chief engineer's or superintendent's office, makes a continuous (not intermittent) record, showing all changes in boiler adjustments that are conducive to either waste or economy.

The Uehling Instrument Co., 71 Broadway, New York, manufacturers of fuel economy equipment, announces that it is now being represented in the New England states by the Smith Engineering & Supply Company, 89 State street, Boston, Mass., manufacturers' agents and engineers, specializing in power plant equipment. Mr. S. W. Smith, president of the latter company, was until very recently associated with the Uehling Instrument Company with headquarters in their New York office.

Starting Properties of D. C. and A. C. Motors

The Various Characteristics of Different Types of Motors Discussed in Relation to Their Starting Properties—Paper Read Before the London Branch of the Association of Mining, Electrical Engineers

By O. L. RECORD

ONE has often to decide what type of motor is best suited for a particular purpose, and consequently a few notes on motor characteristics, with special reference to their starting properties, may be useful.

Direct-Current Machines

(a) Series-wound.—In this type of machine, as the field is excited by the main current, an increase of load increases the strength of the field, and so slows the machine down, and vice versa.

As the torque is proportional to the product of the armature current and field strength, the torque of a series motor would always vary directly as the square of the current were it not that the magnetic circuit becomes saturated above a certain point. In such a theoretical case, doubling the current would give four times the torque, and, at the same time, the speed would be halved, so that the motor would deliver double the power at half the speed. In practice one would obtain considerably more than double the torque and rather more than half the speed.

The curves in Fig. 1 give the relation between current, torque, speed, and power on a typical motor of this kind. It will be seen that the motor automatically adjusts itself to the load, taking a heavy load at a low speed and a light load at a high speed. At starting the torque will be proportional to the current taken, the motor giving full-load torque with full-load current, the latter being limited to the value required by a series starting resistance.

(b) Shunt-wound.—In this type of motor, as the field is excited by a circuit separate from that of the armature, the speed is independent of the armature current except for a slight drop on heavy loads, due to armature resistance voltage drop, and it depends merely on the field current, which again is proportional to the supply voltage. By varying the excitation the speed can be altered quite independently of the load. For a constant field the torque is proportional to the armature current.

Fig. 2 gives curves of torque, speed, and power for this class of motor, and it will be useful to compare this with Fig. 1. In this class also the starting torque will be proportional to the current taken, the motor giving full-load torque with full-load current, and the latter being limited to any desired value by means of a series starting resistance.

(c) Compound-wound.—The effect of the compounding is to give increased starting torque for the same starting current, but at a somewhat lower speed, depending on the proportion of series turns, and also to increase the momentary overload capacity of the machine. On the other hand, the difference in speed between no-load and full-load will be increased.

If even greater constancy of speed is required than that given by a shunt machine, this may be obtained by having a few turns of series winding arranged in opposition to the shunt winding, so that as the load is increased the field is weakened and the speed kept up. This arrangement, however, makes the starting up more difficult, and also decreases the overload capacity of the machine.

Figs. 3 and 4 give the torque, speed, and B.H.P. curves for a compound-wound motor, with cumulative compounding and differential compounding respectively.

Alternating-Current Machines

(a) Polyphase, Asynchronous, or Induction Motors.—In motors of this class the speed is constant except for a slight drop due to slip, amounting to not more than 5 per cent. at full load, and depends solely on the frequency of the supply and the number of poles for which the motor is wound.

The torque varies as the current taken from the line, and both are proportional to the square of the applied voltage. It is important to bear this in mind, for if the voltage only drops as much as 10 per cent., the torque will drop as much as 19 per cent., perhaps sufficient in the case of a heavy load to throw the machine out of step and bring it to a standstill.

Curves of torque, speed, and B.H.P. for a typical motor of this class are given in Fig. 5.

In order to deal with its starting characteristics, it will be necessary to subdivide this class of motor as follows:

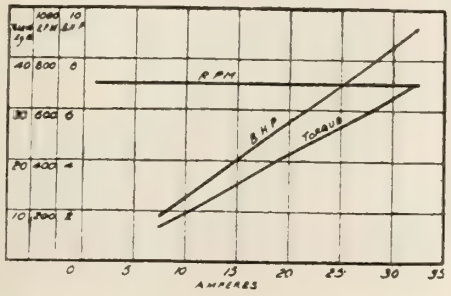
1. Squirrel-cage Type.—These motors may be started in the following ways: First, small motors may be switched direct on to the mains, and will then give a starting torque of about double full-load torque with about six times the normal full-load current. This method of starting is naturally not advisable except in the case of very small machines starting light.

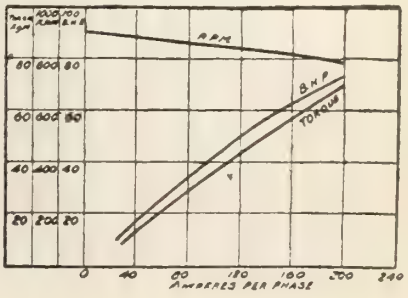
Secondly, by means of stator rheostatic starters. The effect of inserting resistance in the stator is to reduce the voltage across the stator windings, and limit the starting current; but this, unfortunately, results in reducing the torque to a much greater extent—namely, as the square of the voltage, as explained above. If sufficient resistance is inserted to limit the current to even as high a value as two and a half times full-load current, yet the motor will develop a starting torque of only 10 to 25 per cent. of full-load torque; a loose pulley or clutch is therefore necessary for starting in such cases.

Thirdly, by means of star-delta switching in the case of three-phase and series-parallel switching in the case of two-phase motors: If a three-phase motor is started in this way the voltage across each phase winding at starting is reduced to about 0.6 time the running voltage. Consequently the starting current taken will be about 0.36 of the direct-connected starting current, or about two and a half times the normal full-load current. At the same time, the starting torque will be reduced to about 0.36 of full-load torque.

Fourthly, by means of an auto-transformer starter or compensator. The effect of using this type of starter is exactly similar to that obtaining with star-delta starting. Thus the direct-connected starting current and the starting torque are reduced approximately as the square of the reduction in the starting voltage. The voltage tappings very usually employed are 0.5, 0.6, and 0.75 of the line voltage, corresponding to motor starting currents of 1.5, 2.5, and 3.5 times full-load current, and starting torques of about 0.25, 0.36, and 0.56 of full-load torque. The corresponding line currents will be approximately ¾, 1½, and 2½ times full-load current.

2. Slip-ring Type.—Wound-rotor machines are started by inserting resistance in the rotor circuit to limit the starting current to any desired value. When started in this way full-load torque will be obtained with one to one and a quarter time normal full-load current. The relation between torque and current for





other values of the latter is roughly as follows:

50% of full-load current gives 25 % of torque.
55% of ful-load current gives 33 1-3% of torque.
65% of full-load current gives 50 % of torque.
70% of full-load current gives 66 2-3% of torque.
80% of full-load current gives 75 % of torque.

It will therefore be seen that, if a starting torque of 25 per cent. or more of full-load torque with not more than full-load current is required, a slip-ring machine is essential.

3. Self-starting Type.—There is another class of polyphase induction motor having all the advantages of a squirrel-cage machine, but which will start up satisfactorily with a high starting torque without the use of any auxiliary starting apparatus. In motors of this type the rotor winding is composed of two or more sections, which are normally connected so as to give a high resistance at starting, the connection being automatically changed to give a low resistance when the motor has reached 70 to 80 per cent. of its normal speed, by means of a switch operated by a centrifugal governor.

In one motor of this class, one-third of the supply and the number of poles for which the machine is wound, whilst the torque is approximately taken, that is to the load. The characterization curve is similar to those of polyphase machines. Owing to the fact that the field produced by a single-phase current is oscillating and not revolving, as in the case of two or three-phase, a single-phase motor has no inherent starting torque, the latter only being produced when the rotor revolves; consequently an auxiliary or starting phase with a phase-splitting device (consisting usually of a non-inductive resistance in the main winding and a choking coil in the auxiliary winding) has to be provided. Even then the starting torque is but feeble, and a loose pulley must always be employed.

These machines are built of the squirrel-cage and slip-ring types. A squirrel-cage machine will not give more than 10 to 15 per cent. of full-load current. The starting qualities of the slip-ring type are rather better, but even in this case a starting torque of not more than 20 per cent. of full-load torque will be

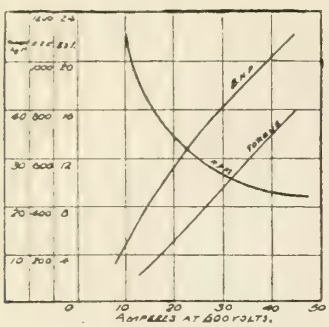


FIG. 1.

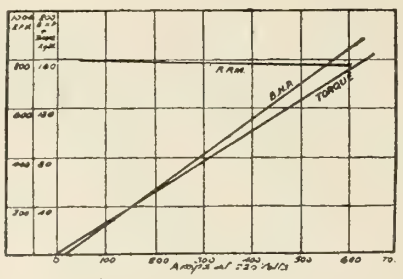

FIG. 2.

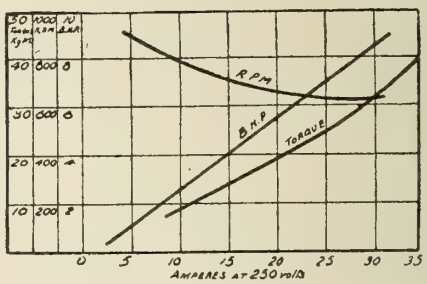

FIG. 3.

only of the rotor copper is in circuit at starting, the remaining two-thirds being open-circuited and connected to a short-circuiting device, which operates when a predetermined speed has been reached.

In another motor of this class the rotor winding is in two or three sections, which are connected in series for starting and in parallel by means of the governor switch when up to 70 to 80 per cent. of the normal speed.

Motors of this class are normally designed to give at starting about 2½ times full-load torque with two to three times full-load current, depending on the size, make, etc. Compare this with the starting torque of about 70 per cent. of full-load torque for three times full-load line current of a squirrel cage motor auto-transformer starter.

If desired, the starting current taken by these motors can be reduced by means of any of the starters employed with squirrel-cage motors, but, of course, with a corresponding reduction in starting torque.

As these motors run as ordinary induction motors, the running characteristics are exactly similar to the latter class of machine.

(b) Single-phase Motors.—1 Induction Type.—As in the case of polyphase induction motors, the speed of these machines depends merely on the frequency obtained with 100 to 125 per cent. of full-load current.

2. Repulsion Induction Type.—These machines are really repulsion motors as far as construction is concerned, and start as such, but are fitted with a centrifugal governor which short-circuits the commutator and lifts the brushes when the motor has got up to speed, so that it continues to run as an ordinary single-phase induction motor. The running characteristics are therefore exactly similar to the latter type, but as against the very feeble starting torque of the split-phase motor they have a starting torque of about 2½ times full-load torque with about 2½ times normal full-load current.

If it is necessary to limit the initial current taken from the mains to a lower value, a plain series starting resistance, such as is used with a direct-current motor, is employed. This tends to raise the power factor so that full load current at starting will give about 1 to 1½ times full-load torque.

ELECTRICALLY DRIVEN PUMPS.

At a meeting of the Institution of Water Engineers, held at Birmingham, Mr. C. F. Bekenn, A.M.Inst.C.E., contributed a paper on "The Application of Turbine-pumps to Water Supply." In the course of the paper the author remarked that while turbine-pumps could be driven by any type of prime mover, he placed the electric motor in the first place as regarded efficiency and convenience. The installation costs, including foundations, were low, and the space occupied was small. The pump and motor required very little attention, as the bearings were automatically lubricated with oil-rings. Low installation costs permitted the sets to be conveniently distributed. They were easily started up, and could also be operated from a distance or automatically stopped and started, either by varying levels in the reservoir or by varying pressures between pre-determined limits. The alternating-current motor was preferable to the direct-current machine owing to the absence of a commutator, and most of the installations at work were driven by A.C. motors. If a heavy current rush on starting was permissible, it was advisable to install squirrel-cage motors, as the turbine-pump, owing to its low-starting torque, could easily be started up by this type of motor. One point that had to be noted was that the slip between synchronous and asynchronous speeds could not be exactly determined, and might vary as much as 2 to 4%. The B.H.P. required to drive the turbine-pump varied as the cube of the speed, so that should the slip be less by, say, 2% than the makers' original estimate, the B.H.P. would be considerably increased, with a proportionate increase of water. For squirrel-cage motors, auto-transformer starters of the oil-immersed type should be installed, with no-volt and overload release on the three circuits, these operating in the stator circuit. The starter consisted of a transformer with tappings on the windings, of varying percentages of the line voltage. The tappings should be selected as best suitable for the starting torque, and as that was not more than 50% of full load torque, a low percentage, say, 25 or 30%, was sufficient. The automatic features were arranged in the "running" position only, because in the "starting" position they would at once break the circuit owing to the rush of current, which was generally two or three times the ordinary running current. This type of starter required only three terminals on the motor and six on the starter—namely, three for the motor and three for the line. In cases where low starting currents were necessary, slip-ring

motors should be installed, as those would start up with 50 per cent. of full load torque using normal running current. With reference to motor terminals, trifurcating boxes were recommended as providing an extremely neat finish and effectively enclosing all the live parts. In large pumping-stations, where the current had to be carried some distance and the motor-power was at least 150B.H.P., the motors could be wound for 6,000 volts, and so dispense with transformers. For motors of less than 150B.H.P. a lower voltage was necessary on account of the difficulties of insulation in the coil windings.

Proceeding to discuss the relative costs of steam and electric pumps, the author gave several examples as showing that economy was on the side of the latter. Thus, the City of Hereford had three electrically driven pumps working off a three-phase, 50-cycle circuit, two sets delivering 60,000 gals. per hour, and the other set delivering 20,000 gals. per hour, against a total lift of 120 ft. in each case. The costs, as recently determined, showed that with electricity at 0.75d. per unit, the cost of electric pumping was 0.5d., as compared with 0.426d. per 100,000 gals., the cost of steam pumping. Those figures included men's wages, lubricating oil, waste, etc. The Newbury District Water Company, early in the year 1912, made careful tests of its compound condensing steam pumps, and of its electric pumps. The latter were driven by direct-current motors, one set having a capacity of 30,000 gals. per hour against 185 ft. lift, one set 20,000 gals. per hour against 150 ft. lift, and a further set 3,000 gals. per hour against 164 ft. The 1912 costs worked out at 1.18d. per 100,000 ft.-gals. for steam, as against 0.957d. for electrically driven pumps, but for 1920 the figures are 2.61d. and 1.576d. respectively. The Chester Waterworks Co. had installed a Diesel engine and dynamo supplying power to drive turbine pumps built by Sulzer and the Rees Roturbo Company, at two separate stations connected by cable. The costs, including all transmission losses and "shut-downs" due to interruption in working consequent on erection of additional plant, came to 0.657d. per 1,000 gals. 100 ft.

Advantages of Flat Furnace Arches

THE recent development of flat arches to a point of distinctive serviceability for boiler furnace construction lies in many cases in simplified design and besides offers greater convenience in the matter of routine repairs. Frequently the design of furnaces calls for reflecting surfaces at various angles and in some special cases some advantages are to be gained in using curved surfaces. The use of sprung arches limits the latitude of construction in these respects and thus many possibilities for furnace improvement go begging.

Also in natural draft furnaces wherein the construction is more or less standard, the support of the necessary curtain wall requires the construction of a separate sprung arch for this purpose although this arch has no function in the combustion of the fuel itself. In designs calling for step-up arches the construction is further complicated. On the other hand flat suspended arches have answered to a considerable extent the criticisms of the usual construction in two respects in particular; viz.: (1) the design eliminates a quite usual source of air leakage into the furnace through the clearance space between arches, and (2) the gaining of increased available headroom which, in the case of forced blast stokers is particularly desirable. In other minor respects flat arches have overcome the effect of sag in sprung arches, in which case no real effective seal can be made either bethe "keying up" with the curtain wall arch, or between the curtain wall and roof, as is the case on B. & W. or similar type boilers.

In the matter of routine repairs of sprung arches, the rebuilding of a bock ring at the fire end requires that the new brick be bonded with the old, and this is rather a difficult matter to do without subsequent cracking. Besides the "keying up" with the curtain wall support arch in place is by no means an easy matter. Here again the flat suspended arch offers convenience of repairs with an increased amount of salvage of the used materials.

As to the proper position, length and pitch of fire arches, it can be stated that there is no exact or precise method of determination, thus giving rise to much diversity of opinion as to these matters among engineers. The only reliable guide is trial and experiments; there are, however, many fundamental principles from a combustion standpoint which determine these factors with some practical degree of accuracy, but too frequently the overall design of boiler and furnace is such that the best proportioning is interfered with, particularly in the matter of the position of the grate with respect to the boiler. In standard construction the art has developed certain relations, which, from the results of actual test and practice appear to offer the most economical results. It is proposed to consider a few of these in this instance.

The function of an ignition arch is to produce as intense a heat reflection at the point of ignition as is possible. The temperatures obtained at this point are, of course, largely dependent upon the sizing and general character of the coal, but most of all to the air supply over this area. In the case of natural draft the temperature possibilities are limited mostly on account of the latter reason, while in forced draft stokers the problem of ignition is simple and controllable. On natural draft a number of trials have shown that the most effective distance between the ignition arch and the fuel bed is from 6 in. to 7 in. and that there is no particular advantage in extending the length of this surface beyond 12 inches insofar as benefiting combustion is concerned. There are, however, many instances where mechanical difficulties have necessitated a departure from this practice. Under forced draft conditions the larger volume of gases requires a greater space between the fuel bed and ignition arch, it being approximately proportional to the amount of increased fuel burned per square foot, per hour. The figures given above apply to a coal rate of 40 lbs. free burning coal per square foot per hour and an 8 in. fuel bed.

The height of the main or fire arch should be such that the intensity of the heat reflection is sufficient to insure continuous combustion the full length of the grate, and in addition provide sufficient volume for the intimate mixture and easy flow of gases of combustion. It is thus evident that the height above the fuel bed is a function of the coal rate per square foot per hour. Under normal natural draft coal rate of 40 lbs. the most effective point is shown by experiment to be between 13 and 20 inches at the front end. However, an arch constructed in accordance with this minimum require that the pitch be such that the increasing sectional area be proportional to the increasing flue gas volume. This steep pitch does not permit of an intimate mixture of gases, particularly over the area of destructive distillation, and unburned hydro-carbons and smoke are the result. These objectionable conditions are removed by raising the front end to the maximum height and using only a slight pitch of about 1 in. per foot. Under forced blast conditions additional furnace volume is required not only on account of the increased coal rate of 60 lbs., excellent conditions were obtained with the main arch 4 ft. above the grate.

Theoretically, the arch projection which gives 100 per cent. over the grate should be correct, but a practical design on this basis is obviously impossible. Good practice calls for a 65 per cent. projection, which gives the maximum length possible, while at the same time providing sufficient exit area from the furnace. Except for this limiting factor and easy flow of air through the fuel bed at the ignition arch, the longer the arch the lower the carbon content of the ash. The disposition to smoke is also accordingly reduced. In the case of forced blast stokers where ample furnace volume is provided, arches of this length are not required as far as combustion of fuel on the grate is concerned.

In general, it can be said that in furnace design the type of boiler and its position with respect to the grate in many cases required deviation from the

(Continued on page 385)

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

IN our last article we arrived at the leading dimensions of a boiler to give 100 h.p. at the standard rating of 34½ lb. water from and at 212 deg. per horse power. These we found to be 72 in. in diameter by 18 ft. long. As the pressure determined on was to be 125 lbs. per square inch we must decide on the thickness of shell and type of riveted joints on the longitudinal seam to carry this pressure, with due allowance for the factor of safety. This factor of safety must be determined by the rules given in the Ontario Government Act, and will vary according to the conditions under which the boiler is built. Following are the rules as given in the handbook issued by the Government.

Factors of Safety

Boilers well designed, well constructed, and made of good material, should be allowed a higher working pressure than boilers inferior in any of the above respects, and unless this is done the superior boiler is placed at a disadvantage and the use of good workmanship and material will be discouraged. To provide for the above, the following rules regarding factors of safety for cylindrical boilers and cylindrical parts of boilers have been adopted.

When cylindrical shells of boilers are made of the best material either in iron or steel with all holes drilled in place from the solid plate, the plates afterwards taken apart and the burrs removed, and all longitudinal seams fitted with double butt straps, each at least ⅝ the thickness of the plates they cover, the seams being double riveted with rivets having an allowance of not more than 75 per cent. over the single shear, and having the circumferential seams constructed so that the per cent. is at least one half that of the longitudinal seam and provided that the boiler has been inspected by inspectors authorized by the act during the whole period of construction in accordance with these regulations, then 4.5 may be used as a factor of safety, but when the above conditions have not been complied with the additions to the following scale must be added to the factor of safety according to the circumstances of each case.

To be added to the factor of 4.5.

A .10 Holes in longitudinal seams, fair and good, but drilled from solid out of place after bending edges of plates.

B .20 Holes in longitudinal seam, fair and good, drilled from solid out of place before bending edges of plate.

C .20 Holes in longitudinal seams, fair and good, punched after bending edges of plates and reamed after assembling.

D .30 Holes in longitudinal seams, fair and good, punched before bending edges of plates and reamed after assembling.

E .07 Holes in circumferential seams, fair and good, drilled from solid out of place after rolling plates.

F .10. Holes in circumferential seams, fair and good, drilled from solid out of place before rolling plates.

G .10 Holes in circumferential seams, fair and good, punched after rolling plates and reamed after assembling.

H .15 Holes in circumferential seams, fair and good, punched before rolling plates and reamed after assembling.

I .70 Longitudinal seams, if double butt straps are not fitted and the said seams are lapped and double riveted.

J .50 Longitudinal seams, if double butt straps are not fitted and the said seams are lap and treble riveted.

K .60 Longitudinal seams, if only single butt straps are fitted and the said seams are double riveted.

L 1.00 Longitudinal seams, when any description of joint is only single riveted or when double straps are used and only one row of rivets in double shear.

M .50 Holes or rivets in longitudinal seams if not fair and not good.

N .20 Holes or rivets in circumferential seams not fair or not good.

O .40 Holes in any seams not properly spaced in crossing.

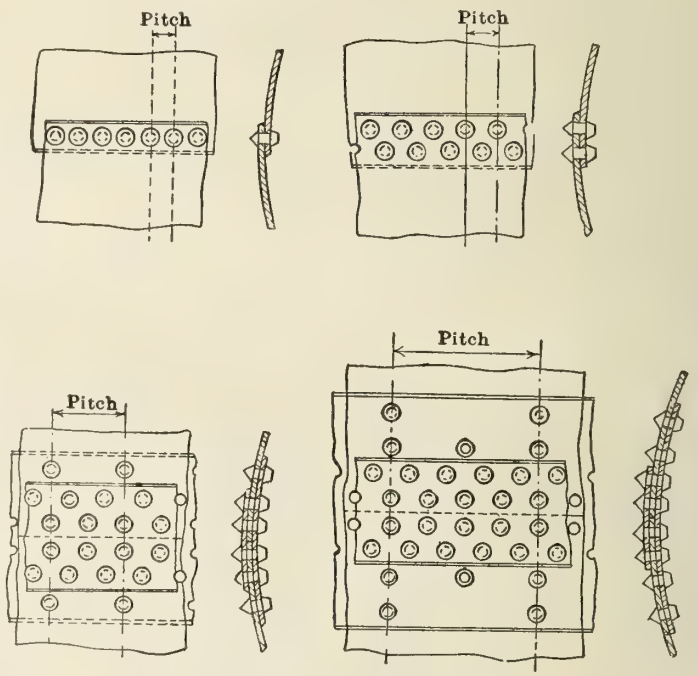
P .40 When material is doubtful and not properly certified in accordance with regulations.

Q .50 If joints are not close fitting the plate being open when boiler is finished or workmanship unsatisfactory.

R .50 If boiler has not been inspected by inspectors authorized by the act during the whole period of construction in accordance with these regulations.

The inspector is allowed some latitude according to his judgment of the circumstances in appying these regulations.

In designing a boiler, the highest factor of safety will be aimed at. This means that the best possible type of joint must be used on the longitudinal seam and that workmanship and material must be good. Before going any further we will therefore discuss the different types of joints.



TYPES OF RIVETED JOINTS

Kinds of Joints

The efficiency of a riveted joint is expressed always as a percentage of the strength of a solid plate. When holes are drilled or punched out of a plate to allow of riveting, the plate is weakened by the amount of metal cut out. If we have a plate of one square inch section, and remove .25 square inches in drilling, the section remaining is only .75, and the resistance of the plate to stress will be only 75 per cent. of its original resistance. This would represent what is known as per cent. of plate strength to solid plate. This is only one factor. The second factor is the proportion that the strength of

the rivets bears to the strength of the solid plate. This will depend on the diameter and number of rivets in the unit section of plate considered, and is also expressed as a percentage. We shall consider the means of arriving at these efficiencies shortly.

There are several styles of riveted joints, and two distinct classes. The lap type of joint is so called because it is made by lapping the edges of the plate over each other and riveting them together. The second type is known as a butt joint and is made by bringing together the edges of the plates to be joined and placing a broad plate over them, riveting all three plates together. In many cases two cover plates are used. These two types of joints are subject to various modifications. Thus a lap joint may be single, double, or treble riveted and the rivets may be placed in regular rows or in staggered rows, known as chain or zig-zag riveting. The butt strap joint may be made with one or two straps, with equal or unequal straps, with double, treble or quadruple riveting. The type of joint selected will depend upon the pressure to be carried, cost of manufacture and rules of the province in which the boiler is to work. The cut here shown illustrates the type of joints mentioned above.

To Find Efficiency of Joint

The efficiency of a riveted joint varies with the diameter of rivets, pitch of rivets, number of rivets in a pitch, and the thickness of the plate. In considering riveted joint efficiency, the unit of plate area considered is always contained within a pitch or between the centre lines of two adjacent rivets. Where there is more than one row of rivets the pitch of the rivets in the outer row is taken. We will explain each type as we come to them. The most simple is of course the single riveted lap joint. Suppose we have a plate of 5-16 inch in thickness, and with ⅝ rivets pitch 2 inches. We have to consider the strength of the joint as compared to the solid plate. We will consider the plate to be of 60,000 lbs. tensile strength. We shall therefore have a section, before any drilling is done, of 2 x 5-16 = ⅝ square inches. This section will have a resistance of 60,000 x ⅝ = 37,500 lbs. Now, after drilling, the amount of metal removed will be in diameter just equal to the diameter of one rivet because in the section we are considering there will be just half a hole on each side. A glance at the sketch which shows the pitch of line passing through the centre of rivets will make this clear. Therefore the amount of metal removed will be equal to the diameter of one rivet multiplied by the thickness of the plate, or

$\frac{5}{8} \times \frac{5}{16} = \frac{25}{128}$. This amount subtracted from the original area will give the section remaining, and if this remainder be divided by the original section we will have a fraction, representing the proportion of original section remaining. To express this as a percentage we multiply by 100. Now to follow out the procedure step by step.

Let

P = pitch.
d = diameter of rivet.
t = thickness of plate.

We have a plate section of pitch P, and thickness t, the area being Pt. The rivet area will be equal to dt, so that when the holes are drilled we shall have

$$Pt - dt = P - d$$

the t on each side cancelling out.

The proportion of plate section remaining is $\frac{P-d}{P}$ and the percentage of plate to solid plate is $\frac{P-d}{P} \times 100$. Substituting figures, we get

$$Pt = 2 \times \frac{5}{16}$$

$$dt = \frac{5}{8} \times \frac{5}{16}$$

$$Pt - dt = 2 \times \frac{5}{16} - \frac{5}{8} \times \frac{5}{16}$$

$$P - d = 2 - \frac{5}{8}$$

$$\frac{P-d}{P} = \frac{2 - \frac{5}{8}}{2}$$

$$\frac{P-d}{P} \times 100 = \frac{2 - \frac{5}{8}}{2} \times 100$$

$$= \frac{2 - .625}{2} \times 100$$

$$= \frac{1.375}{2} \times 100$$

$$= 68.75$$

So that the proportion of plate strength to solid plate is 68.75 per cent.

This formula is always used, and may be set down

$\frac{P-D}{P} \times 100 =$ per cent. of plate strength to solid plate.

In the Ontario regulations the plate efficiency is symbolized by the letters Kt, so the formula is

$$\frac{P-D}{P} \times 100 \text{ Kt}$$

The next point to consider is the efficiency of the rivets in the joint. This is the proportion that the area of the rivet in the pitch limit bears to the unit section of plate. As rivets are not as strong in resisting shearing stresses as they are in resisting tensile stresses, an allowance must be made for this difference. The Ontario regulations use the constant C, and this is expressed

$$C = \frac{\text{Shearing strength of rivets}}{\text{Tensile strength of plate}}$$

C may be taken as

.85 for iron rivets in iron plates
.70 for steel rivets in steel plates.
.65 for iron rivets in steel plates.

In the joint we are considering there is but one rivet in the pitch, and as there are but two plates which the rivets pass through they are in single shear. We will then have an area of d × d × .7854, divided by the area of the unit section, which is P × t. This is expressed in the formula:

$\frac{a \times n}{P \times t} \times C \times 100 =$ per cent. of rivets' strength to solid plate.

So we have

$$\frac{5 \times 5 \times .7854 \times 1 \times 16 \times C}{8 \times 8 \times 2 \times 5} \times 100 = \text{Ks}$$

This worked out becomes, if we take C as .85

$$\frac{5 \times .7854 \times 85}{8} = 41.72 \text{ per cent.}$$

If we neglected the constant C we would get about 49 per cent. This lowest percentage is the one used in calculating the working pressure of the boiler. In our next article we will consider the strength of riveted joints of more complicated design.

ADVANTAGES OF FLAT ARCHES

(Continued from page 283)

principles of good practice. With boilers of the B. & W. type or Heine type where sufficient headroom obtains, the opportunities for flexible design are not interfered with, but in the case of Stirling, Conolly and similar types, practical conditions have to be overcome, and in many cases at the expense of efficiency. It is obviously quite difficult to formulate a code of furnace practice to cover all special conditions, but on the other hand those principles established by usage and corroborated by experiment should offer the furnace designer considerable insurance against failure.

Many engineers are at the present time prone to accept the fantastic and gamble with untried principles. Again there are others who opine that the mere changing of a detail is a cure for all ills. The best guide after all that can be said, is trial and experiment.

A. S. M. E. MEETING

The 1920 annual meeting of the American Society of Mechanical Engineers will be held in the Engineering Societies Building, 29 West 39th Street, New York City, from December 7 to December 10.

Sessions will be held on the subjects of appraisal and valuation, and the application of engineering to woodworking.

The newly founded profession sections on management, power, fuels, machine shop, railroads and textiles will also conduct sessions to consider the vital problems in their field. In addition a number of valuable papers will be presented at general sessions.

A memorial session for Dr. Brashear is planned, as a fitting tribute to his life and work.

The Open Type Locomotive Feed Water Heater

The Theory and Practice of Feed Water Heating by This Type of Heater is Discussed by the Author in a Paper Read Before the A.S.M.E.

By THOMAS C. McBRIDE

THE use of feedwater heaters on locomotives dates back to the beginning of the locomotive itself. There are records of the application of an "open" or "injection" type heater to a locomotive in England in 1827, and an English patent of 1828 describes a tubular heater for the same purpose. Ross Winans of Baltimore applied tubular heaters to two types of Baltimore & Ohio railroad locomotives in 1836. It is worthy of note that the desirability of the feedwater heater for the locomotive was recognized at these early dates, although it must be appreciated that the advantages possible at that time were proportionately greater than at the present time because of the low-steam pressure then in use.

There is much of interest in the history of locomotive feedwater heating in a paper, Feedwater Heaters and Their Development by J. Snowden Bell which was presented at the fiftieth annual meeting of the American Railway Master Mechanics Association, in June, 1918. Every conceivable type of heater and all possible sources of heat, even the hot ashes, seem to have been proposed or tried, and in view of the amount of study that has been given to the subject it seems rather remarkable that locomotive feedwater heating is not now in more general use. Possibly the reason lies in the fact that it is only in comparatively recent years that the essentials of heater performance and pump operation have been understood. Furthermore the small size of the locomotives formerly in general use limited the saving per locomotive, and the general adoption of the injector, because of its simplicity and convenience, rendered feedwater heating impossible, for injectors heat the water which they use to such an extent by live steam that there is little or no opportunity for further heating.

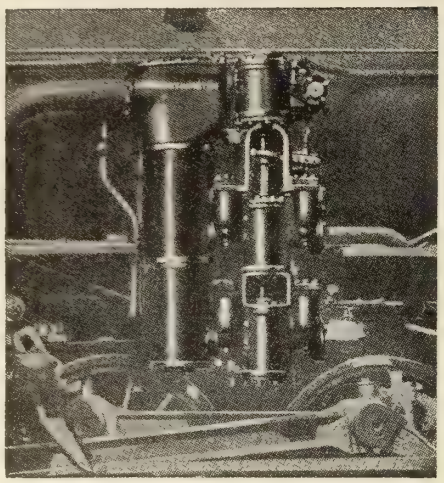


FIG. 1—PUMP AND HEATER APPLIED TO MIKADO LOCOMOTIVE.

There are two possible sources in a locomotive from which otherwise waste heat may be obtained to heat the feedwater: (a) the waste gases in the smokebox or stack, (b) the exhaust steam. Stationary practice with economizers indicates the waste-gas heaters cannot be supplied with cold water because the accumulation of condensation and soot on them seriously interferes with their efficiency. It is, therefore, necessary to turn to the exhaust steam for the source of heat and to develop this type of heater first, leaving the waste-gas heater for later development as may be found either necessary or advisable.

The exhaust steam heater may be either of the open or injection type in which the exhaust steam comes into direct contact with the cold feedwater so that the water condensed from this exhaust steam is added to and mixed with this feedwater; or, of the closed or surface type in which the heat from the condensation of the exhaust steam passes to the feedwater through thin sheets of metal, generally in the form of thin brass tubes. Practically all of the development work to date that has been at all successful has considered only the surface type. There are a great many heaters of this type in service in Europe, but there are objections to it for locomotive use. It is a complex and delicate structure; it also wastes the water condensed from the exhaust steam with its heat or raises complications as to saving it, and it requires enough exhaust steam to heat all of the feedwater. On the other hand, the open or injection type of heater necessarily recovers both the water condensed from the exhaust steam and its heat so that both are returned direct to the boiler with the water taken from the tender. Less water is therefore taken from the tender and less exhaust steam is required for the heating.

Description of a New Type of Heater

With these thoughts in mind, the author has devised a system of locomotive feedwater heating which makes use of a heater of the open type which is manufactured and marketed by the Worthington Pump and Machinery Corporation. The system follows marine practice in heaters of this type, and the pump and heater have been combined into a single unit which can be conveniently attached to the side of the locomotive

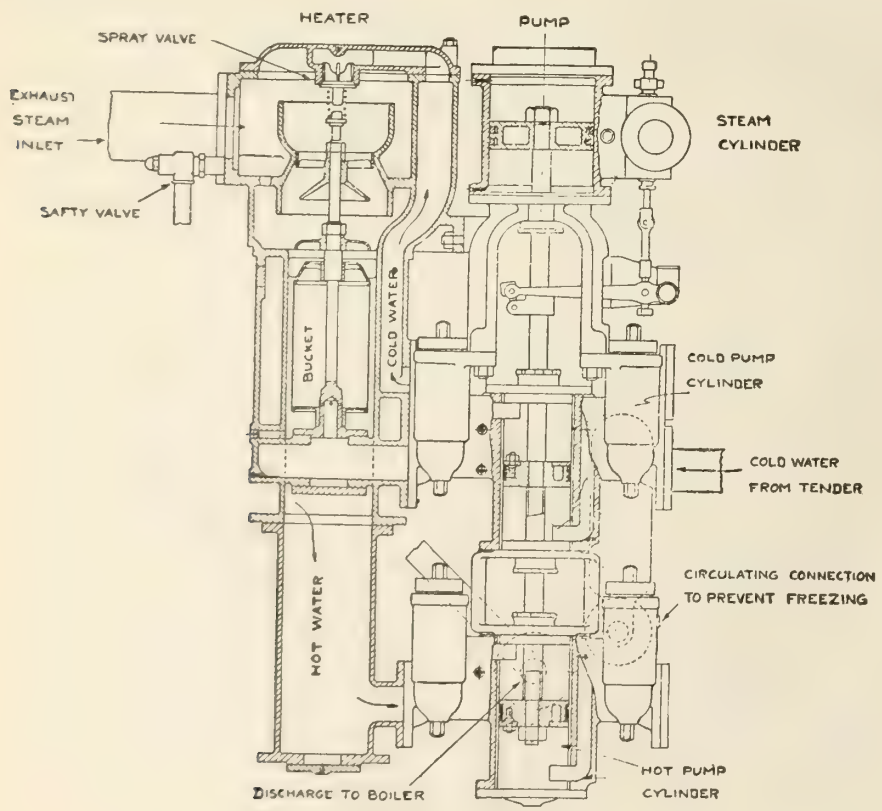

FIG. 2—SECTION OF THE HEATER.

boiler as is the practice with air-brake compressors. Fig. 1 shows a unit with a capacity of 60,000 lb. of feedwater per hour in service on a Mikado locomotive. Fig. 2 is a sectional view of the heater and pump. In these illustrations the heater is shown at the left, the feed pump at the right.

The heater is a simple cast-iron box, the upper part of which is supplied with exhaust steam taken from the locomotive through holes cut in the back of the cylinder saddle and a pipe which has in it a stop check valve and an oil separator, the latter having a small hole in it so that there is a continuous drip for the oil.

The pump is of the vertical type attached to the side of the heater by the various pipe connections. The steam cylinder of the pump is at the top, and it has two water cylinders clearly shown in the illustrations, both operated from the same piston rod. The water cylinder in the middle of the pump takes cold water from the tender and delivers it through a port in the side of the heater to a spray valve in the extreme top of the heater where it is sprayed into the exhaust steam that fills the top of the heater. This condenses as much of the exhaust steam as the water needs to heat it, and the mixture, dropping to the bottom of the heater is taken by the other pump cylinder and delivered to the boiler through the usual check valve. The pump cylinder which takes the cold water from the tender and delivers it to the heater is really a measuring device which feeds into the heat approximately the same amount of water that the lower pump cylinder takes out of the heater, but the varying amounts of exhaust steam condensed in heating the feedwater cause a tendency for a slight excess of water to accumulate so that in time the heater would become flooded. This is prevented by returning this excess water under the control of a bucket in the heater to the pump cylinder in the middle of the pump through one of its pump-suction valves serving this water alone.

The pump is driven by saturated steam taken from the locomotive boiler through a 1-in. steam pipe and controlled by a throttle valve in the cab within convenient reach of the engineer. The exhaust steam from the pump is led into the back of the stop check valve where it mixes with the exhaust steam from the locomotive, and passes with it through the oil separator to the heater. These pipe connections as well as the cold-water pipe from the tender passing back of the air-brake compressor and the feed line from the lower pump cylinder to the boiler are shown in Fig. 1.

The adoption of the open heater for the locomotive may seem a radical step, but from this description it will be evident that no new elements are used. The heater itself is of a general type that has been in use in marine service for at least twenty years. The open heater with the oil separator to remove the oil from the exhaust steam before it enters the heater because of its merits has been almost universally adopted for stationary plants. One of these heater and pump units was thoroughy tested out on the locomotive test plant of the Pennsylvania Railroad at Altoona, Pa., in 1917, and has been in operation on road service since October 1918. Three more units have been in operation for approximately a year on pooled locomotives and have given no trouble other than the usual pump maintenance. Nothing has developed indicating that the open heater as a type is not well adapted to the locomotive and the coal and water savings have been so marked as to be evident to the crew.

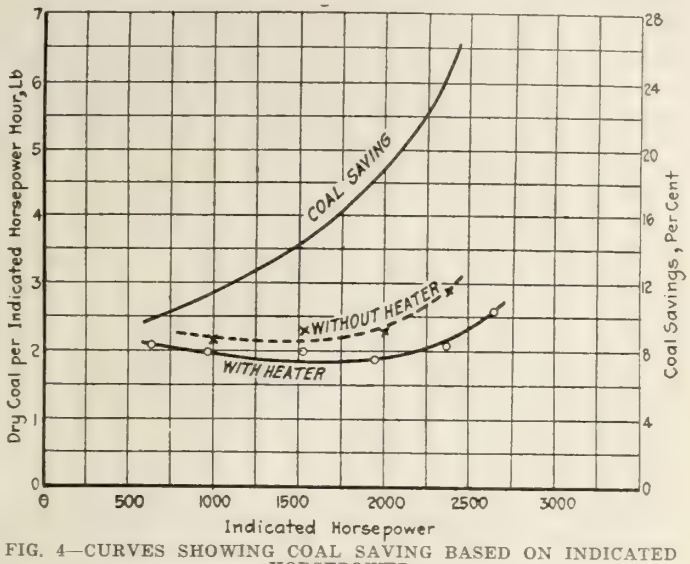

FIG. 4—CURVES SHOWING COAL SAVING BASED ON INDICATED HORSEPOWER.

The pump is much easier to operate than an injector as it requires only a slight turn of the 1-in. throttle valve to either start it or to make it run faster or slower as the boiler may need more or less water. It does not require priming and can be operated continuously at low capacities where the injector must be stopped and started periodically.

The feed pump should not be used, as is often done with the injector, to fill the boiler on the down grade and then be shut off as long as possible on the up grade; first, because there is not as much inducement or necessity for operating it in this way, and secondly, because the prime purpose of the heater is to recover heat and it can only do so when the locomotive is pulling and exhaust steam is available for the heating. If the injector is operated continuously and maintains a constant water level in the boiler each pound of steam generated will require 1276 B. t.u. from the fire with 200 lb. steam pressure, 150 deg. superheat, and 40 deg. water in the tender. If the injector is shut off each pound of steam will require somewhat more than 925 B.t.u.

so that the amount of steam from the same fire will be increased less than 38 per cent. It will later be shown that under the same conditions the feedwater heater would increase the amount of steam about 13.6 per cent. The feedwater heater will, therefore, materially increase the amount of steam on the up grade, although not to the extent possible in the case of the injector and should be depended upon to feed the boiler entirely on the up grade with the consequent greater amount of heat recovered from the exhaust and more nearly constant water level in the boiler.

Advantages of Locomotive Feedwater Heating

It is not possible to make an exact general statement of the advantages to be obtained from locomotive feedwater heating, because much depends on the particular locomotive to which the heater is to be attached, the capacity at which it is worked, the temperature of the water in the tender, and the basis on which the advantages obtained are stated.

We are able to base our notions as to the advantages of feedwater heating on the results obtained in stationary practice where the coal saving is very properly considered as equivalent to the reduction in the amount of heat necessary to evaporate the water because of the higher temperature at which the water is delivered to the boiler. In the case of the locomotive, however, with its very complicated relations of the different operations that are going on, and the very wide range of capacity through which the boiler is operated, there is generally a much greater coal saving than in stationary practice. Three factors enter into the final result. These are as follows:

1. The reduction in the amount of heat required to evaporate the water in the boiler, which might be called the *heat saving due to the feedwater heater.*

2. The reduction in the amount of heat required results in a greater reduction in the amount of coal required because of the better efficiency of the boiler at the lower rate of combustion. These two factors give the *coal saving based on water evaporated.*

3. The exhaust steam taken by the heater from the exhaust ports of the locomotive reduces slightly the back pressure in the locomotive and should show some advantage. All three factors combined will give *the coal saving based on indicated horsepower.*

An analysis of these three factors will show the coal and water saving referred to the steam that is used in the locomotive cylinders, and therefore, the minimum saving since it does not include the saving in generating the steam used by the auxiliaries. It is necessary to make this analysis partly theoretical assuming certain constant operating conditions in order that a fair comparison may be made of the effect of the heater on different locomotives and at different locomotive capacities. It can only apply to the coal burned while running since the heater can have no influence while standing or at terminals. The percentage of coal saving due to the heater, and to a lesser extent the percentage of water saving when based on ton miles, the month, or the year will be less than the percentage while running by an amount determined by the use made of the locomotives.

Heat Saving Due to Feedwater Heater

The first factor, the heat saving, is determined by the amount the feedwater is heated by exhaust steam taken from the locomotive. This factor will evidently be greatest when the tender-water temperature is low and when the exhaust steam pressure in the heater is highest, as this pressure determines the temperature to which the feedwater can be heated. This pressure will be highest when the locomotive is working hard, and when the exhaust steam for the heater is taken from that part of the steam valve chests or cylinder saddles where its pressure is greatest.

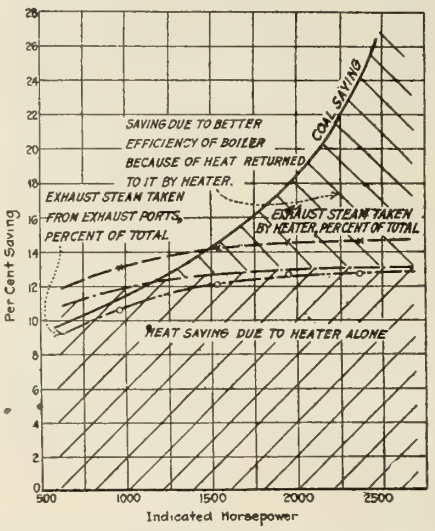

FIG. 5—ANALYSIS OF COAL SAVING BASED ON I.H.P. WITH EXHAUST STEAM LIFT AVAILABLE FOR DRAFT.

The exhaust steam from the feed pump need not be be wasted, since it can be and is used in the feedwater heater, but this use prevents the recovery of the same amount of exhaust steam and heat from the exhaust of the locomotive. The amount of steam used by the feed pump is, therefore, a direct charge against the saving due to feedwater heating as compared to injector operation when considered in the light of recovery of waste heat from the locomotive exhaust, or when estimated by the temperature rise of the feedwater in the heater.

Test plant results and actual daily operation on the road with superheated steam locomotives show that the feedwater heater described can be depended on to effect a reduction of at least 10 per cent. in the summer time and 12 per cent. in the winter time in the amount of heat required to evaporate the water and superheat the steam. This heat saving will not be constant at these figures but will vary with the capacity at which the locomotive is worked because the steam pressure in the heater determines the temperature to which the feedwater can be heated. These figures can, however, be conservatively accepted as representing average working conditions at which the greater part of the coal is burned.

The tabulation given in Table 1 is based on heating the feedwater to 215 deg. This is quite conservative as it has been found easily possible to obtain this temperature with this heater even with tender-water temperatures of 40 deg. and on locomotives worked at less than two-thirds of their maximum capacity. The tabulation shows that greater heat saving is possible with saturated than with superheated steam locomotives; therefore the percentage of coal saving will be greater with saturated than with superheated steam locomotives. Table 2 gives the exhaust steam required for the heating. The percentage of water saved is shown by table 3.

The allowances which have been made for the steam used by the feed pump are based on carefully conducted tests of the feed pump and heater which show that this feed pump when running with saturated and fairly wet steam required for its operation 2 per cent. or less of the weight of steam generated by the boiler. The pump, therefore, uses 2 per cent. or less of the heat required from the fire by the saturated steam locomotive, but in the case of superheated steam locomotive the feed pump will re-

Table 1—Heat Saving Due to Feedwater Heater.

Assumed steam pressure in branch pipe, lb. per sq. in.	200	200	200	200

70 to 215 deg.	...	145.0	...	145.0
Heat saving, per cent.	14.7	12.5	13.7	11.6
Total heat required by locomotive with feed pump as compared to injector operation, per cent.	102	102	101.75	101.75
Heat saving in locomotive with heater as compared to injector operation, per cent.	15.0	12.75	13.94	11.80
Heat required, per cent.	87.0	89.25	87.81	89.95
Heat saving as compared to injector operation	13.0	10.75	12.2	10.05

quire but about 1.75 per cent. of the heat from the fire of the locomotive because of the greater heat required to generate the superheated steam. The tabulation is based on steam leaving the branch pipe at 200 lb. pressure with 150 deg. superheat in the superheated steam locomotive and gives value of the heat saving, water saving, and percentage of exhaust steam required by the heater for tender-water temperatures of 40 and 70 deg. respectively. The term "heat content" is used to express the amount of heat in the water or steam above that in water at 32 deg. fahr. temperature.

From the tabulation it will also be noted that in the case of the feedwater heater for the locomotive, because of its comparison to injector operation, it is not possible to apply the usual short rule customary in stationary practice stating that a certain number of degrees of heating of the feedwater results in 1 per cent. heat saving, but rather that it is more exact to state, assuming the conditions of the table, that in the saturated steam locomotive, after the first 23.8 or 23.2 deg. heating, each 11.9 or 11.6 deg. of heating represents 1 per cent. heat saving, and that in the superheated steam locomotive after the first 22.3 or 21.8 deg. of heating each 12.8 or 12.5 deg. of heating represents 1 per cent. heat saving, the first figures in each case applying with 40 deg. and the second figures with 70 deg. water temperature.

European practice, as far as the author is informed, involves the use of tubular heaters differing only in details of their construction and discharging to the track the water condensed from the exhaust steam in the heater, thus losing both this water and its heat, necessarily with some additional steam that must be blown through the heater to prevent it becoming air-bound. These locomotives require 2 per cent. more water than when operated with the injector because of the steam used by the feed pump and discharge to the track from 15 to 18 per cent. of this with from 2.6 to 1.8 per cent. of the heat of the saturated and 2.4 to 1.6 per cent. of the heat of the superheated steam locomotive in the water alone for 40 and 70 deg. water respectively. There are a few surface heaters in operation on locomotives in this country in which this water is saved by pumping it back to the tender through filters to remove the oil, but in doing so approximately 80 per cent. of its heat is lost by radiation from the tender. This loss of heat from the locomotive with the surface heater does not count directly against the coal saving since it is supplied by the exhaust steam, but it does count indirectly since it decreases the amount of exhaust steam left available for the draft. The open heater is more economical in the use of exhaust steam and leaves more available for the draft with the possibility of lower back pressure and saving because of this.

The locomotive with the open heater or the surface heater saving the water condensed from the exhaust steam requires the extra 2 per cent. steam to operate the feed pump, but from 15 to 18 per cent. of this 102 per cent. is recovered, so that the net water saving is from 13.3 to 16.4 per cent. respectively for the assumed summer and winter conditions as compared to injector operation.

Coal Saving Based on Water Evaporated

To combine these results with the second factor in order to obtain the coal saving based on water evaporated it is necessary to consider particular locomotives since the second factor involves the change in the efficiency of the boiler with varying boiler capacity. For this purpose the curves of Fig. 3 have been prepared. The curves on the left marked A are on the basis of 10 per cent. heat saving; those on the right marked B on the basis of 12 per cent. heat saving. The upper solid curves marked "Injector" are test plant results of a Consolidation, Atlantic, and Mikado type locomotive respectively, and show the total amount of water evaporated per hour against dry coal fired. The dotted curves marked "Heater" for each of these three locomotives show the amount of water that would have been evaporated by the same amount of coal with a feedwater heater reducing by 10 per cent. respectively the amount of heat required to evaporate the water and superheat the steam. The vertical distances between the solid and dotted curves represent the amount of coal saved and these quantities are shown in the lower set of curves. This lower set of curves, therefore, shows the coal saving based on water evaporated due to the feedwater heater that follows a reduction of 10 per cent. and 12 per cent. respectively in the amount of heat necessary to evaporate the water and superheat the steam. These curves show that the feedwater heater attached to a locomotive will effect a coal saving beginning at low capacities practically identical with the heat saving, or the coal saving which we have been accustomed to in stationary practice, but which increases at first gradually and then more rapidly as the capacity of the locomotive is increased, reaching values twice or more than twice these figures as the maximum capacity of the locomotive is approached.

It would be difficult to credit this result were it not warranted theoretically by the second factor mentioned above, and had it not been confirmed in test plant results with a wide margin to spare. A study of the upper curves in connection with the lower curves of both figures will show that the very great coal saving possible is accompanied by an increase in steaming capacity due to the feedwater heater and that it should be possible to work the locomotive with the heater at greater steaming capacities than are possible with the injector but how much greater would depend largely on the particular locomotive.

Referring to the lower set of curves of Fig. 3 and assuming that the Consolidation locomotive would be operated normally at a steaming rate of say 25,000 lb. per hr., it is noted that the 10 and 12 per cent. heat savings assumed as summer and winter conditions would result in 14 and 16.6 per cent. coal savings respectively. Assuming that the Atlantic type locomotive would also normally be operated at a steaming rate of 25,000 lb. per hr., the coal saving would be 12.8 and 14.5 per cent. respectively. Assuming that the Mikado locomotive is hand fired and operated at a steaming rate of 37,500 lb. per hr., the coal saving would be 12 and 14.2 per cent. respectively.

On the other hand, it is altogether possible that advantage should be taken of the feedwater heater either in increased speed or increased hauling capacity and the same amount of coal burned with it as would have been burned if the locomotive had operated with the injector. In this case, the summertime 10 per cent. heat saving would result in a

$$\frac{100}{100 - 10}$$

per cent. steaming capacity or 11.1 per cent. increase; and the 12 per cent. heat saving would result in a

$$\frac{100}{100 - 12}$$

per cent. steaming capacity or an increase of 13.6 per cent. But as compared to injection operation at this increased steaming capacity the coal saving in the Consolidation locomotive would be 15.5 and 19 per cent., in the Atlantic locomotive 13.3 and 15.5 per cent., and in the Mikado locomotive 13 and 15.3 per cent. respectively.

The feedwater heater does not appear to as great advantage in the Mikado locomotive as in the other type locomotives because it is not as fully loaded.

Table 2—Exhaust Steam Required For Heating

Assumed tender water temperature, deg. fahr.	40	70
B.t.u. required to heat one pound of feedwater to 215 deg.:

Exhaust steam to heater from feed pump, per cent.	2	2
Exhaust steam from exhaust ports of locomotive required by surface heater, per cent.	16	13
by open heater, per cent.	13.8	11.5

If the Mikado locomotive was operated at a steaming rate of say 50,000 lb. per hr., the assumed 10 and 12 per cent. saving would have resulted in a 15 and 17.3 per cent. coal-saving respectively, and if advantage had been taken of the feedwater heater for the increased capacity burning the same amount of coal as with the injector the coal saving would have been 18 and 21.2 per cent. respectively.

Coal Saving Based on Indicated horsepower

Any modification which the third factor makes in the combination of the first two factors as shown in Fig 3, leading up to the coal saving per indicated horsepower, must be but slight and depend on the particular locomotive. Saturated steam locomotives should show a further gain of a few per cent. from reduced back pressure. Test plant records show some reduction in this back pressure in superheated steam locomotives accompanied by a reduction in superheat and indicate that, at least until further tests are made, this factor should not be considered for superheated steam locomotives.

The curves of Fig. 4 are test plant results of a Mikado locomotive, comparing its operation with the injector and with the feedwater heater described in this paper. Table 4 shows the heat recovered by the feedwater heater and Table 5 the coal saving and increase in efficiency. They show a coal saving curve of the same general character, but slightly higher than the curve for the Mikado locomotive of Fig. 3, based on water evaporated, although the tests were made under practically identical operating conditions as to temperatures and pressures.

The coal-saving curve of Fig. 4 has been reproduced in Fig. 5, and a curve added showing the reduction in the amount of heat required to evaporate the water and superheat the steam, because of the heater. The cross-hatched area above this curve shows the additional saving presumably all due to the better efficiency of the boiler with the reduced amount of heat required from the fire because of the heat recovered by the heater.

Exhaust Steam Available for the Draft

The question has been raised as to whether the exhaust steam taken from the locomotive by the feedwater heater would cause trouble with the draft. This question could be analyzed from the partly theoretical curves of Fig 3, but as actual operating conditions are of more interest, curves have been added to Fig. 5 showing the total exhaust steam taken by the heater and the exhaust steam taken from the exhaust ports of the locomotive. The distance between these two curves represents the exhaust steam furnished by the feed pump to the heater. It is noted that the curve of exhaust steam taken from the exhaust port is below the curve of coal saving. The feedwater heater, therefore, reduced the amount of coal burned at a greater rate than it reduced the amount of exhaust steam, so that there was surplus of exhaust steam left available for the draft and no necessity for reducing the size of the blast nozzle and consequent possibility of reduced back pressure in the locomotive cylinders because of this heater. For instance, at 2,000 i.h.p., the reduction in the amount of coal burned was 18 per cent., and in the amount of exhaust steam, 12½ per cent. As compared to injector operation, 82 parts of coal had to be burned and 87½ parts of exhaust steam were left available for the draft to burn it.

Table 3—Water Saving Due to Feedwater Heater

Steam for locomotive cylinders, per cent.	100	100
Steam required for feed pump, per cent.	2	2
Water required by locomotive with surface heater discharging water condensed from exhaust steam to track, as compared to injector operation, per cent.	102	102
Exhaust steam condensed in heating feed water, per cent.:		
0.18×102	18.4	...
0.15×102	...	15.3
Water required by locomotive with open heater or surface heater saving condensation from exhaust steam compared to injector operation, per cent.	83.6	86.7
Water saving, per cent.	16.4	13.3

Table 4—Heat Recovered by the Feedwater Heater.

Test No.	1	2	3	4
Steam to engine, lb. per min.	314.5	492.8	599.1	757.3
Steam to feed pump, lb. per min.	7.4	10.5	12.5	14.6
Steam to safety valve, lb. per min.	0.8	0.7	2.1	5.5
Exhaust steam condensed, lb. per min.	42.3	71.4	90.0	113.7
Heat in steam, B.t.u. per min. to engines	402,749	639,063	780,867	996,531

With heater	965	1534	1949	2373
Coal per indicated horsepower hour, lb.:				
Without heater	2.2	2.3	2.3	2.9
With heater	2.0	2.0	1.9	2.2
Coal saving by feed heating, per cent.	9.1	13.1	17.4	24.7
Drawbar horsepower:				
Without heater	824	1289	1690	2019
With heater	783	1293	1679	2055
Thermal efficiency of locomotive, per cent.:				
Without heater	7.0	6.7	6.7	5.4
With heater	7.6	8.0	8.6	7.8
Increase in efficiency with heater, per cent.	8.5	19.4	28.3	44.4

Conclusions

The feedwater heater on the locomotive may be used to reduce the coal and water consumption working the locomotive at the same capacity as with the injector or to increase the capacity of the locomotive, or partly for both, as occasion demands. It will save coal and water all the time, and permit of increased capacity when needed.

The feedwater heater might be considered as alternate to large size of locomotive boiler and grate as a means to coal economy, if for any reason both are not considered advisable or possible for still further economy. This feature is well illustrated in Fig. 3, where it is noted that the Consolidation locomotive with an open heater gives more steam per pound of coal burned than the Mikado locomtive without a heater up to 2800 lb. of dry coal fired per hr., with the 10 per cent. heat saving, and up to 3000 lb. per hr. with the 12 per cent. heat saving. Test plant records show the Consolidation with heater burns less coal per indicated horsepower than the Mikado without heater up to a still greater rate of coal fired. The smaller amount of coal burned by the Consolidation locomotive at terminals and its lower first cost and maintenance cost favor it still further in the comparison.

Viewed from the standpoint of coal and water saving, the adoption of the heater becomes a question of interest on first cost, depreciation and maintenance cost against these savings. Viewed from the standpoint of increased capacity, the question becomes one as to whether the feedwater heater does not offer increased capacity at the lowest first cost, especially if, as in the case of the comparison of the Consolidation locomotive with and the Mikado locomotive without a heater, the adoption of the heater permits of the use of a simpler and less costly type of locomotive.

The feedwater heater offers a solution of the pressing problem of these times, when so many fairly old and small locomotives have outgrown their usefulness because they are not large enough for present-day demands. The feedwater heater will not only increase the capacity of these locomotiyes, or what might be called their economical operating capacity, at a comparatively low cost and with little change in them, but it will also show a larger percentage of coal saving because of their full loading than would be obtained with present-day larger locomotives.

The feedwater heater offers the peculiar advantage of being of most assistance to the locomotive just at the time when the locomotive needs assistance. It offers its greatest saving in fuel or increase in capacity in the winter time, and these advantages are not ef-

fected by reduced steam pressure or superheat, but continue in spite of them and at a proportionately greater rate.

The study of the subject of the feedwater heater for the locomotive that has been reviewed in this paper has resulted in the adoption of the open-feedwater heater as a type. It has been developed into a unit with the pump, so that it can be attached to the locomotive at minimum expense. These units have been thoroughly tested both on the test plant and on the road, and every confidence is felt in their ability to meet the severe requirements of locomotive service, and to effect the maximum possible saving of fuel and water with a minimum amount of attention from the crew.

STANDARDIZATION OF STRUCTURAL SHAPES

On the entrance of the United States into the war with the Central Powers there came a demand for immediate increase in ship construction which, in turn, meant increased production by the steel mills. To increase production to the minimum and to simplify order practice, a conference of steel makers was held in Washington on July 2, 1917, at which was adopted American standard practice for structural steel for ships.

The result of this action proved distinctly beneficial both to the mills and the shipyards, but was not followed immediately by a standardization of and a reduction in the number of structural shapes used at the yards, and in consequence the Emergency Fleet Corporation undertook an investigation to ascertain definitely the number of structural shapes used in shipbuilding and the possibility of their standardization and reduction in number. As an outcome of these investigations carried on by Mr. Fred T. Llewellyn in the Division of Steel Ship Construction under Daniel H. Cox, Manager, it became possible to determine what were the sections in most general use and at the same time were brought out clearly the divergencies in the sections rolled by different mills

At a conference of steel makers held in Philadelphia on November, 19, 1918, inasmuch as the British standard sections of ship channels and shipbuilding bulb angles appeared to be better adapted to economical manufacture than the American standard sections and inasmuch further as the new rolls which had been turned in recent years to produce sections conformed in general to British standards, it was decided that therefore American standard sections should be discontinued and that rolls not then to British standards be redressed at as early a date as possible to roll such sections as closely as possible to British standards and this particularly in view of the further fact that the adoption of British standard sections would enable American mills to compete on an even basis for ship steel wherever utilized in shipyards, either at home or overseas.

The British standard sections thus adopted as American standards were those adopted by the British Engineering Standards Association as published in 1903, and it was not known that this Association had undertaken a revision of the British standard sections in 1913, work on which, however, had been suspended by reason of the war activities. When, however, through the trade press, information as to what had been done in the United States came to the attention of the British Engineering Standards Association, that Association advised American steel makers as to the situation and later through their secretary, Mr. LeMaistre, expressed their desire to have the American structural trade co-operate with the British Engineering Standards Association in the formulation of common Anglo-American standards for structural shapes.

At the instance of the Association of American Steel Manufacturers, a Sectional Committee on Steel Shapes was organized under the auspices of the American Engineering Standards Committee. This Sectional Committee is composed as follows:

American Bureau of Shipping—Captain C. A. McAllister; David Arnott; John Martin.

American Society of Civil Engineers—J. H. Edwards; J. B. French; H. G. Balcolm.

Association of American Steel Manufacturers—R. B. Woodworth, (Chairman); G. H. Blakely; Geo. E. Thackeray.

Railway Car Manufacturers' Association—A. E. Ostrander.

Society of Naval Architects and Marine Engineers—Fred T. Llewellyn; E. H. Rigg; J. W. Stewart.

United States Navy — Commander C. M. Simmers; Lieut. Com. H. D. Rouzer.

The Sectional Committee gave very careful consideration to the entire routine of structural practice in the United States not only as it affects the profiles of structural shapes themselves, but also as regards methods of order practice, calculation and publication of weights, areas and properties, etc., with the idea to insure as far as possible a complete accord between makers and users wherever the sections rolled in English - speaking lands were used. At its meeting held on April 27, 1920, it formulated its recommendations for submission to its sponsor organizations, to the American Engineering Standards Committee and to the British Engineering Standards Association as a basis for common Anglo-American standards, and its conclusions are now to go before these organizations for further discussion and endorsement. The essential features of these recommendations are:—

1. The adoption of the decimal system for the expression of dimensions, thicknesses and other elements of order practice.

2. The adoption as an Anglo-American standard of the standard order practice adopted by the Association of American Steel Manufacturers on February 20, 1920, under which structural shapes are to be ordered by weights per foot and not by thickness.

3. The adoption as an Anglo-American standard of American standard practice as it relates to ranges of thicknesses, methods of computation and methods of publication.

4. The adoption of definite ranges in thicknesses of angles and other structural shapes, under which are established two zones of variations between minimum and maximum thicknesses. Under .60-in. thick variations are fixed at four one-hundredths inch (0.04-in.) and above .60-in. thick at eight one hundredths inch (0.08-in.)

5. Included in the list of angles is an equal angle (9x9) and four unequal angles (8x4, 9x4, 9x6 and 10x4) which are not now rolled in United States, but are subject to the considerations which weigh with manufacturers when new rolls are contemplated.

6. The adoption of a new line of bulb angle sections as proposed by the British Engineering Standards Association that are recommended on account of their greater efficiency as compared with present British and American standards.

7. The adoption of a single line of channel sections with a 5 deg. flange taper to displace the present two American lines, the structural line with its flange taper 9 deg. 27′ 42″ and the shipbuilding line with its flange taper of 2 deg. This line of channel sections is not quite in accord with that proposed by the British Engineering Standards Association, but is believed to be more suitable to the requirements of the American trade and better proportioned.

8. The adoption of a new line of beam sections to take the place of the present American standards adopted in 1896. These sections have wider flanges than present American standards and do not agree very closely with the British proposals, but are believed by the Sectional Committee to be more nearly in accord with the recent developments in the fabrication of buildings and bridges.

A recent communication to the French Academy of Sciences, states that coal has been discovered in the region of Port Gueydon, French North Africa. This coal appears to belong to very extensive beds lying in the region mentioned. Analysis taken have revealed the following composition:—"Moisture, 1.05 to 1.15 per cent.; ash, 37.15 to 53.65 per cent.; volatile matter, 8.05 to 12.27 per cent.; fixed carbon and sulphur, 37.25 to 49.45 per cent; the calorific value varies from 3960 to 5390 calories.

The Council of Action

THE creating of what is known as a Council of Action by the leading trades unions in Great Britain, with the avowed object of dictating to the Government its policy on certain questions of national importance, creates, as Mr. Lloyd George plainly states, "the most formidable challenge ever given to democracy." There can be no doubt that the people of Great Britain generally are war weary, and not labor alone. The greatest beneficiaries of the war were the trades unionists, and some of the capitalists, though not by any means all. It is the great middle classes who suffered the most and got nothing at all out of it who would probably be the most unwilling to see their country embarked on another period of war. Their voice, however, is not heard above the clamor made by the representatives of organized labor, which, after all, is by no means a majority of the community, but, on the other hand, a relatively small portion. Organized labor in Great Britain has, since the war, been frankly out to get everything it could possibly extort, and has not been afraid, in this endeavor, to attempt the complete paralysis of the country. The great transportation strike should have taught their representatives that when they go in opposition to the general public they are comparatively powerless, and it is quite possible that in making their threats of a general strike in the event of Britain taking action in Poland, they did so with their tongues in their cheeks. As a matter of fact, the British Prime Minister says that the aims of the Government and the aims of the Council of Action are practically the same, but he plainly and positively states that were they not, "dictation would be resisted by all means in the power of the Government." Trades unions can serve an excellent purpose, and have been instrumental in making life a more pleasant thing for the trades unionist. When they start to assume the role of the Government it is time to call a halt. While every right-minded person wishes to see labor, both organized and unorganized, get all the good out of life that it is possible to obtain, no sane person wishes to see any minority of the people holding a club over the rest. Lloyd George is to be congratulated on his uncompromising stand against such coercion.

The Engineer's Opportunity

THE organization of the Federated Engineering Societies at their recent conference at Washington, D.C., is certainly a step in the right direction.

About 75 branches of the engineering profession were represented, these including Civil, Mechanical, Mining, Electrical, Sanitary, Heating, Marine, Agricultural, Radio, Refrigerating, Fire Protection, Industrial, Automotive, Military Engineers, Architects and Geologists, etc.

The need of such a body has been felt for years, but the problem was to successfully affiliate the various interests. The action taken at Washington has removed the only remaining nigger in the woodpile.

The object of this newly formed body is both ambitious and essential. They desire to raise the standing of engineers generally, and to teach the public how much they really depend upon the engineering profession. Any society, club or organization, the chief object of which is the advancement of the knowledge and practice of engineering and the application of applied sciences, and which is not organized for commercial purposes, is eligible for membership.

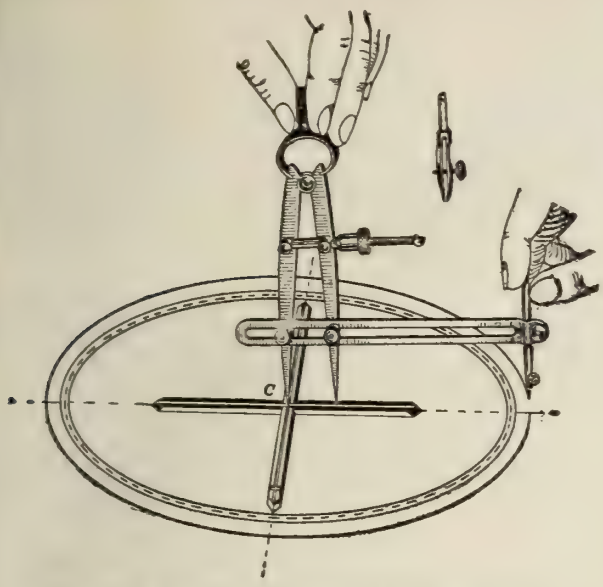
The success of this society, as we see it from our side of the line, depends entirely upon the engineers themselves. With proper support this body should grow to be a powerful influence and will form the official mouthpiece, so to speak, for engineers all over the country.

To our mind the forming of this society should be greeted with great enthusiasm by engineers in general and they should rally to its support. An opportunity such as this affords is not to be treated lightly. We will watch with interest the development of the organization, and once more emphasize the necessity of every engineer becoming a live member and actual booster.

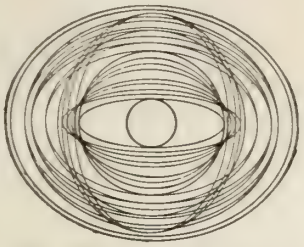
—Thomas in the Detroit "News."
"City folks get themselves into the durnedest messes."

REID ELLIPSOGRAPH

Daniel C. Reid, 2717 N. Croskey Street, Philadelphia, Pa., has placed on the market what is known as the Reid Ellipsograph. This instrument is claimed to draw all kinds of ellipses or ovals, from 1½ in. up to 12 in. major axis, and describes a perfect ellipse in one operation.



THIS VIEW SHOWS THE INSTRUMENT IN USE.

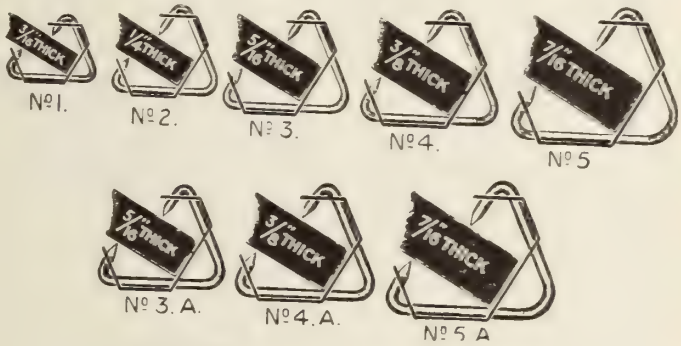


THE WORK ACCOMPLISHED

The instrument is provided with pen and pen parts, and can also be used for drawing circles up to 12 in. diam. It can also be used as an ordinary divider. This announcement will no doubt appeal to draftsmen, designers, illustrators, architects, etc. To illustrate its construction we show the illustrations herewith.

UNIVERSAL BELT FASTENERS

An improved type of belt fastener, known as the "Universal," has been placed on the Canadian market by the Climax Company, of 244 Lemoine Street, Montreal. These fasteners are the result of careful study and exhaustive experiment on the part of the makers, and are universal in character. They are equally efficient in rubber, balata, leather or cotton belting, and are made in six-inch lengths, of sizes varying to take belts from 3-16 to 7-16 inch in thickness.

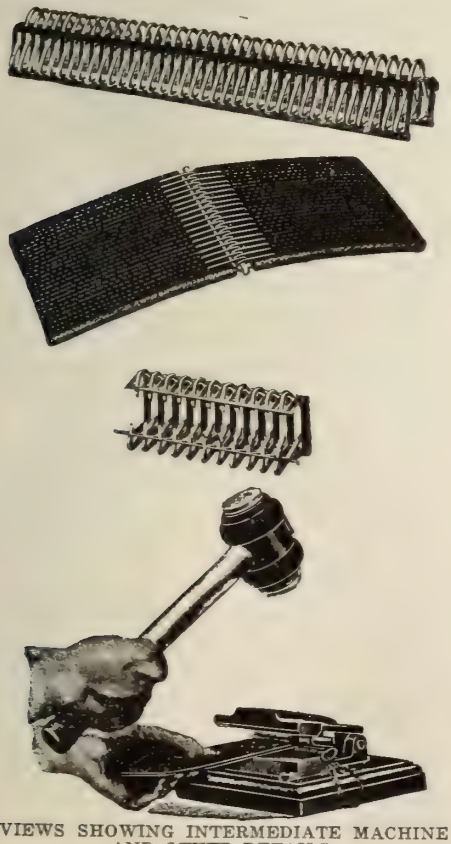


VIEW SHOWING THE VARIOUS SIZE HOOKS.

The individual hooks are held in position by a metal frame which retains the hooks in the same relative position all the time the hooks are being forced into the belt. When the hooks are flush with the belt the frame slips off freely. The fasteners are made in two gauges of wire, the larger sizes being adapted to meet the requirements of the user who has extra heavy belts running over small pulleys.

On the intermediate fasteners the wire can be laced into the belt with a simple hammering tool, economically and efficiently. For the larger sizes, a special lacing machine is preferable. On the smallest sizes, the lacing can be performed by using a hammer and a wooden block, the metal frame assuring perfect alignment during the operation. The great advantage of the metal frame is that it prevents the hooks from twisting to one side or the other while being forced into the belt. The fasteners are made with a series of hooks having long and short legs, the short legs entering the belt on the pulley side, this method minimizing the metal contact on the pulley and reducing the possible slip. The hooks do not meet in the belt, but are individually staggered, thus increasing the effective pull.

The fasteners can be cut to any desired length without fear of wasted ends, as the metal frame keeps the pieces intact. A pair of narrow scissors are provided for cutting the metal frame.



VIEWS SHOWING INTERMEDIATE MACHINE AND OTHER DETAILS.

THE HEAVIER TYPE MACHINE.

We have received Bulletin B-410 of the Yarnall-Waring Co., describing the Yarway seatless and Yarway double tightening blow-off valves. There is an interesting diagram showing the cost of leaky blow-off valves. This shows by means of a curve loss in water and coal in dollars per month and per year, and water loss in thousands of gallons per month. These valves are constructed to conform to the A. S. M. E. standards. The double tightening valve was originally made to use in conjunction with the Yarway seatless valve in places where the boiler laws require the use of two valves. Anybody interested in blow-off valves can obtain a copy of the bulletin by requesting one from the makers, Yarnall & Waring Co., Chestnut Hill, Philadelphia.

Want To Get Heat.—A strong committee has been appointed by the Board of Directors of the Chamber of Commerce of Chatham, to meet representatives of the Chatham Heating Co. The object of the committee is to try and prevent a repetition of last year's experience, when business suffered to a considerable extent due to a lack of heat, which it is claimed the company failed to supply.

TRADE GOSSIP

The Canadian Pacific Railway Company announce the apopintment of Mr. F. S. Rosseter to be acting Superintendent, Chapleau Division, with headquarters at Chapleau, vice Mr. W. R. Boucher, who has received a month's leave of absence.

Want To Export Coal. — The chairman of the Dominion Railway Commission is receiving many applications for permission to export coal. There has been an order against the export of any coal from August 1st, and the applicants claim that they had the contracts made and vessels chartered to carry the coal before the order came out. They, therefore, claim that they should be allowed to export those orders.

Car Shops for Toronto.—It is understood that representatives of car-building firms have been looking over the ground with a view to establishing a street car building shop in Toronto. This is irrespective of the continuation of the Toronto Street Railway's shops for car manufacturing. There is a probability also that the plant of the Dominion Shipbuilding Co. may be utilised for this purpose.

Alberta's Coal Export Increased. — The output of the Alberta mines for the six months ending July 31st was 3,043,940 tons, as compared with 2,068,-907 tons for the same period last year. There has been more coal marketed during the six months period than in any corresponding period in the history of coal mining in Alberta. The exportations for the six months show a 50 per cent. increase.

Coal Situation Better.—According to Mr. J. D. A. Morrow, vice-president of the National Coal Association in the United States, and who has just returned from a ten days' trip, the situation is better than it was. Due to the increased car supply, a big increase in the coal shipped to New England and the North-West besides other parts of the country had taken place. The production for last week, he estimated, was about 11 000 000 tons, which is still 1,000,000 tons under the normal requirements.

Hydro Business Last Year. — In a statement made by the Hydro Electric Commissioners, the following figures are given. The number of municipalities taking power has increased in ten years from 12 to 115, and the power distributed from 25,000 to 225,000. There are 12 rural systems, 23 companies, and five Government industries. The total assets at the Falls and in the municipalities amount to $40.693,070 and the accumulated reserves $7,654,370 and the surplus $2,177,934.

Mine Sells Entire Output.—The Blue Diamond Coal Mines at Brule, Alta., have contracted their entire output for the next six months, according to J. P. Bickell. Mr. Bickell is a director of the McIntyre Porcupine Mines, Ltd., which has just purchased the coal mining company. The contract is for the west, and the entire capacity is required, even if it exceeds 2,000 tons per day. The output is at present about 600 tons per day, and it will require over a year to bring the output up to 2,000 tons per day.

Starting in Vancouver.—The Britannia Wire Rope Co., is getting in shape to operate at their plant on Granville Island, B.C. The machinery for most of the plant is now on the way from England. C. H. Gill is the British director, and Robert Gibson, managing director.

Conference in Fall.—The second great Industrial Conference will be held in Canada some time in October or November. An appropriation was made by Parliament at last session to cover the expenses of the conferences, and it is expected that the experience gained at the last conference will result in making this one an even more representative gathering of labor, capital and the general public.

New Rates Contract. — The Special Scale Committee of coal operators and miners sitting in District 18, Calgary, have completed their labors. The agreement is between the Western Canada Coal Operators' Association and District 18, of the United Mine Workers of America. The agreement provides for an all-round increase, and is in force till April next, and retroactive from March last.

Baldwin Plant Ready Soon. — The plant at Ashbridge's Bay will be ready for operation in about three weeks' time. it is expected. There will be a staff of between eight and nine hundred men employed at the beginning, and when the plant has worked up to full capacity it will employ 6,000. A large number of the men are coming direct from the works in Wales and incidentally among these are included some who were in Moscow with the general manager of the plant here, Mr. Cound.

Bounty for Iron Industry.—The Hon. William Sloane, Minister of Mines for the Province of British Columbia, speaking about the possibility of an iron smelting industry in the Pacific Coast Province, pointed out that the present bounty offered by the Provincial Government would amount on a 300-ton plan to something like $1,000,000. He stated that Mr. Fleming, of the Canadian Collieries (Dunsmuir), was looking into the situation, as their company thought of entering into the industry. As to the claim that there would be no market for the product, Mr. Sloan thought there would be no difficulty on that score, as the Pacific Coast could be supplied at prices beyond the competition of eastern furnaces. In any case, he thought the Federal Government could be induced to build extensive car shops for the National Railways at one of the western terminals, which would absorb a large percentage of the output of a 300-ton furnace.

Herbert Johnson, of the Armstrong Whitworth Company of Canada, has been appointed general superintendent of the plant at Longueuil. Lawrence Russell, the general manager, will be in charge of the sales.

Have Bought Factory.—The Dominion Cone Company have sold their factory at 14 Morrow Avenue to Tarbox Bros., specialty manufacturers. The building is of two storey brick, with a basement, the total floor space being 12,500 square feet. The frontage is 40 feet The deal was closed through Robins, Ltd.

Brantford City Engineer.—Mr. Frank Adams, city engineer of Chatham, has been appointed city engineer of Brantford, at a salary of $3,600 for the present year, and $4,000 for next year. Mr. Adams is an old Brantford boy, and well acquainted with the locality, and its special problems. He will take up his duties on September 15th next, succeeding the late Major Harry Jones.

ACCIDENT PREVENTION

Accidents and accident prevention in machine building are discussed in Bulletin No. 256 published by the United States Bureau of Labour Statistics. The booklet gives the result of an investigation to ascertain the frequency and severity of accidents in the machine-building industry, and to study and analyse these accidents in such a way as to supply the information necessary for effective safety work, To this end the report seeks, as far as possible, to locate the accident hazards in particular departments and occupations, to discover the reason and causes for the occurrence of accidents, and to point out some of the more successful methods for their prevention. The investigation was limited to certain selected plants representing the more important classes of product, and covered in all 194 plants. Accident rates are analysed for the industry as a whole, by character of products, and by departments. Inability to speak English as related to accidents, safety organization, direct safeguarding methods in machine building, and machine design as a factor of safety, are among the subjects discussed.

OPTICAL INSTRUMENTS

Optical equipment for the inspection of flat surfaces and the comparison of standards, is a line of tools now being placed on the market by the Van Keuren Company of Boston, Mass. By means of these instruments comparisons can be made to one-half a wave length of light, which for daylight is approximately 0.00001 inch. It is claimed that the working flats of the set will register an accuracy of 0.000005 inch and that of the master flat to within 0.00000025 inch. Full instructions are included with the instruments and the equipment is intended for shop use.

CONE PULLEY BELT SHIFTERS

Speaking on the above subject before the summer conference of the National Safety Council (Engineering Section), Mr. H. E. Somes, electrical engineer of the Chevrolet Motor Co., made the following statements:

At your last meeting, I volunteered to obtain time studies on mechanical belt shifters for cone pulley belts and on the hand method. After going through a number of large machine shops, I was very much surprised to find that, with the exception of an isolated instance, belt shifter devices for cone pulley belts were not used; and due to that fact, and also the short period of time left to investigate this subject, I have been unable as yet to obtain the time studies. One of our factory managers who has a successful belt shifter installed expressed it as his opinion that a green workman can shift cone pulley belts by means of the belt shifter as rapidly as an experienced workmen can shift them by hand —with the additional advantage that in doing so he is safeguarded from injury. However, in my investigations on this subject, I have been convinced of the fact that mechanical belt shifters can be developed that will shift belts on cone pulleys more rapidly than by means of the hand shifting method—much more safely and efficiently and without serious injury to the belt itself. Possibly such shifters have already been developed.

The problem, however, seems to be where should cone pulley belt shifters be required? Such a shifter has its maximum value when it is installed on a machine where belts are shifted many times per day. If a saving can be realized in the workman's time, due to an improved method of shifting belts and the machine itself has a greater capacity, these advantages will become more apparent as the number of belt changes increases. Usually the advantages become of lesser importance as the number of shiftings decreases.

I would submit, therefore, at this time that mechanical belt shifters for cone pulleys are particularly adapted to shop installations where frequent shiftings of the belts from one step cone to another is necessary. Among such installations we find the tool room, the maintenance or the repair shops, and many other types of manufacturing machine shops which can possibly be classified wherein belt shifting is a necessity.

Considering the modern manufacturing machine shop, such as the automobile manufacturing plant, we are struck at once by the fact that belt shifting is very uncommon, and in fact in many cases, if the manufacturer could obtain them, single purpose machines would be purchased.

In a shop of the type commonly called production machine shop, we find that an individual machine is tooled up for a single job, and that frequently this machine runs several years without having any change made in the method of manufacture or the speed of either feed or spindle.

Illustrating this point, I was in Flint, Mich., recently and went to our plant to see a screw machine which had been fitted with a mechanical belt shifter. I asked the operator what he thought of the shifter in question and how he found he could shift the belt by means of the shifter. He replied that he had been employed on that particular job for approximately eight months; he thought the belt shifter was very satisfactory, but that he never used it to shift belts with, excepting to satisfy himself that the shifter would work. This condition exists throughout that entire plant.

The field where the belt shifter would give greater service would undoubtedly be in a shop not engaged in production manufacturing, but rather where on account of the special nature of the different jobs, wide variations in the spindle speeds are necessary. This would also apply to drill press operations where the step cone pulleys are not on the machine itself and where one is exposed within twelve or eighteen inches of the floor. Drill presses, excepting where they are used over long periods of time on a single operation, require a large number of changes throughout the working day, owing to the different sizes of drills which may be used on an individual job.

While observing a belt shifter at Flint, several days ago, I noticed that it seemed to be very satisfactory in shifting from high to low; but in shifting from low to high speeds, I noted that the belt curled and that it was very difficult to make this shifting. The plant engineer advised me that the shifter had been thoroughly satisfactory until the belt became oil soaked from long use.

In order, however, that we may obtain accurate information as to the advantages of using mechanical belt shifters over the hand shifting method, and also in order that we may know definitely whether a satisfactory shifter has been developed, our company has arranged to conduct a test on several types of shifters. This test will be strictly impartial, and as a result, we hope to learn whether by using a mechanical shifter the belt is injured, and whether the shifters are satisfactory after the belt has become thoroughly oil soaked and very pliable.

Why pay $1.50, instead of 2¼c a pound for about 286 pounds of superfluous iron in a steam trap? That is literally what you do when you purchase a cumbersome steam trap of the bucket or float type, with its array of troublesome floats, levers, valves, water gauges, bowls, and other **unnecessary** parts.

The Steam Trap Sarco does everything that the larger, heavier and more complicated traps do. Yet, it has but one moving part and weighs about 6% as much.

STEAM TRAP SARCO

because of its simplicity and light weight, sells for about one-third the price of other makes.

A Sarco saves money in the purchase price as well as in installation cost, for it requires no platform building, no supports, no pit digging. Can be easily and quickly installed at any point on the line.

Let us send you a Sarco on 30 days' trial. If you are willing to part with it at the end of that time, send it back and the trial will cost you nothing.

Write for Booklet J-17 and full information.

15 Sales Offices Backed by the 100% Standard of Quality

THE Canadian Fairbanks-Morse Company Limited reaches out to you through its sales houses and offers the service and satisfaction that is assured by its 100% standard of quality and service.

To be able to turn to an institution that dominates its field in the industrial world is to safeguard the character of the merchandise you buy. To deal with an organizationthat is doing business at your very door puts upon the man you know that "responsibility which is the conscience of business."

Every one of these 15 offices has been established to bring to you the full advantages and benefit that have made The Canadian Fairbanks-Morse Co. Limited a national institution. Here in these offices is offered everything mechanical that your business requires — they centralize your purchasing—group your orders—bulk your shipments and send but one invoice. And when you buy from The Canadian Fairbanks-Morse Co. Limited you are guaranteed the 100% standard of quality and service in product and organization.

Make our nearest office your buying centre—our catalogue is your buying guide —our 100% quality seal your guarantee.

WHY DO YOU ADVERTISE

When You Are Behind In Deliveries ?

THIS seems to be a very natural question, and the answer involves the discussion of a vital policy of this business—a policy that is fundamental.

If we were building a business for to-day our policy would vary from day to day with the temporary changes with which every business has to contend.

But we are building for the time to come and we hope that this business will become many times greater than it is to-day. Without the proper foundation it would undergo violent changes dependent upon temporary national, local or even imaginary conditions.

If we should permit ourselves to become inflated with self-confidence when business conditions are favorable, restricting our selling and advertising activities, and go down in the dumps when conditions are not so favorable, this business would not amount to any more than the existing conditions would make of it.

We say right now, without reservations, that we hope, regardless of how aggressive and efficient our manufacturing department may be, that it will never be able to catch up with our selling organization.

If our efforts should be halted in the middle of the road in times of liberal buying to wait on the manufacturing department, there might come a time when the manufacturing department would have to suspend operations while waiting on the sales organization.

With such a policy we would be running around in a circle, disorganizing one day and reorganizing the next.

The greater the demand for our product, the quicker the turnover for merchants; and the more frequent the turnovers, the larger is the volume of profit.

In this business advertising is a sales policy—the same as our policy of maintaining a sales organization—and we might as well consider the elimination of one as the other. Neither will be eliminated, as this business needs both if we are building for the future.

We hope the idea will never creep into this organization that there will be any let-up in aggressive methods, which might suggest that when business is good there is no occasion for work and when business is poor it is too hard to get.

We constantly have in mind that the American people are much more concerned in their own affairs than in ours, and if we should restrict our selling and advertising activities they will begin to forget us—and this would be our fault.

We are going ahead with the idea of increasing the present momentum in favor of our goods; and if conditions should turn face about, our dealers and ourselves will be in a better position to hurdle obstacles than if we originated a policy for each condition as it arose.

DEPARTMENT OF LABOUR

Ontario Government

Minister: Hon W. R. Rollo **Deputy Minister: W. A. Riddell, Ph.D.**

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a **Stationary** steam plant of 50 B.H.P. or over, and everyone operating a **Hoisting** steam plant working at a pressure of 20 pounds or over, irrespective of horsepower and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a certificate from the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers.. Application forms will be forwarded upon request.

All applications should be mailed to the Chairman of the Board. W. C. McGhie, Department of Labour, 15 Queen's Park, Toronto.

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering, the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., ch. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, 15 Queen's Park, Toronto. D. M. Medcalf, Chief Inspector of Steam Boilers.

MONCRIEFF'S

"UNIFIC" GAUGE GLASSES

The British Navy uses "Moncrieff's" "Unific". It is the kind that lasts. It is a special feature of the "Unific" that it does not readily corrode; resists extreme changes of temperature and withstands the highest working steam pressure. In consequence it has a long life, justifies a higher price than the soda lime glasses, and is, indeed, the more economical purchase in the end.

THE ANDERSON
MODEL "D" STEAM TRAP
Allows No Escape Of Live Steam.

The valve is always locked with at least three inches of water, thus the escape of live steam is rendered impossible.

The **Anderson** will lift water at any back pressure five pounds less than the pressure at the trap:

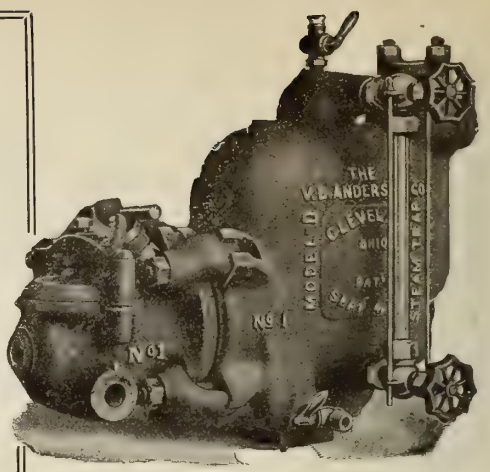
A strainer and sediment chamber prevents sediment and scale from getting into the valve.

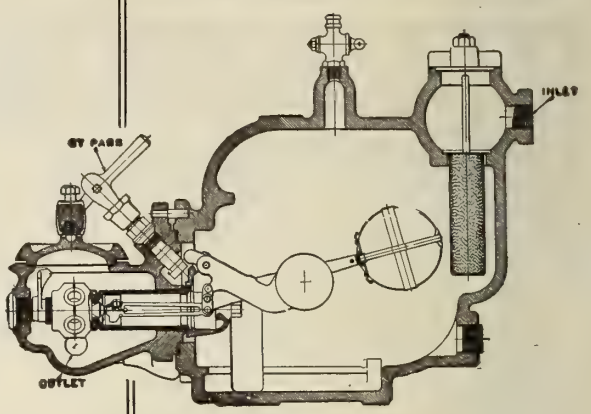
To ascertain whether the trap is working properly, a glance at the gauge glass, fitted to the trap, is sufficient.

The valve and valve seat can both be removed without breaking a steam joint or pipe connection.

The **Anderson Model "D" Steam Trap** is accurate in every detail. Built of materials best suited for the purpose. Every part interchangeable.

Full particulars of these and other points will be forwarded immediately upon receipt of your request.



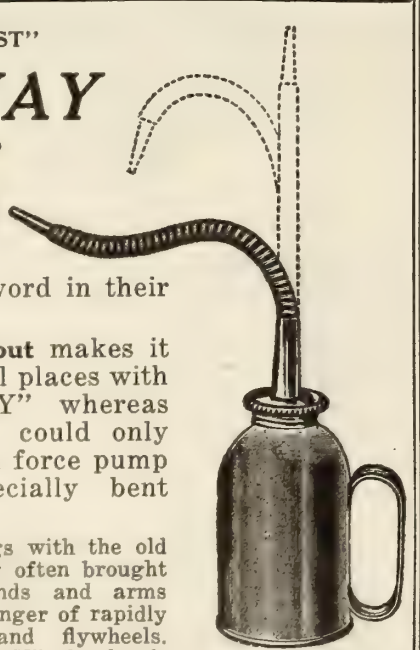


The V. D. Anderson & Company

1935 West 96th St., Cleveland, Ohio.

"SAFETY FIRST"

ALL-WAY
RAILROAD
OILERS



are the latest word in their line.

The **flexible spout** makes it possible to oil all places with one "ALL-WAY" whereas previously they could only be reached with force pump cans with specially bent spouts.

Lubricating bearings with the old straight spout oiler often brought the engineer's hands and arms very close to the danger of rapidly revolving gears and flywheels. With the "ALL-WAY" the bending of the spout removes this danger. Sizes No. 4, 1 pint—10 in. spout. No. 5, 1 quart—11 in. spout.

If your dealer cannot supply you write us.

We also manufacture the well-known "All-Way" Oil Can—saves you 50% of your oil bill.

The Design of Moore Steam Turbines Prevents Steam Leaks

Ample surfaces at the joints have been provided to prevent leakage of steam—also the number of vertical joints have been reduced to a minimum. In a turbine having numerous vertical joints it is almost impossible to prevent leakage and consequent loss of efficiency in operation.

The careful designing to prevent all steam leakage is but one feature of Moore Steam Turbines. Send for our booklet. It explains fully the others.

Moore Steam Turbine Corporation

Wellsville New York U.S.A.

HOMESTEAD VALVES

Positive-Acting Quarter-Turn Valves

Homesteads are "positive-acting" in each position. When open there is a straight, unobstructed flow. When closed they are positively tight. All Homesteads are constructed with the patented Homestead principle, which locks the valve tightly to the seat when closed.

One-quarter of a turn only is necessary to open and close Homestead Valves. Adopt them. You'll save time, trouble and expense.

Our catalog contains some interesting information.

POWER HOUSE BUYERS' DIRECTORY

If what you want is not listed here write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of a advertising contract.

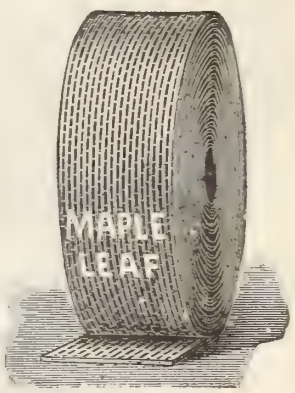
Dominion Belting Company, Limited

Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata; as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

ROBB

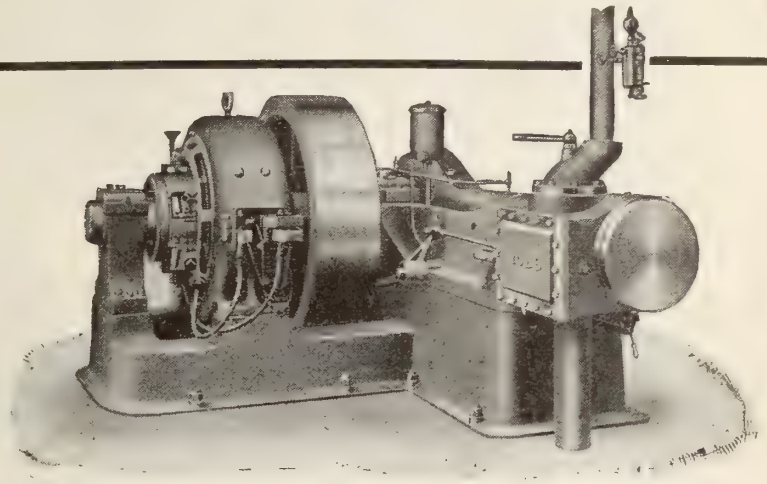
For Quality Equipment

POWER PLANTS

We specialize in the design and construction of power plant equipment. Our engineers are prepared to investigate your problems and advise on the most economical machinery for your needs.

We can supply Corliss, Slide-Valve, Vertical, Horizontal, Simple and Compound Engines, and Water tube, Return tubular, Improved Scotch Marine, and Portable Boilers.

Robb Equipment is known to engineers and power plant superintendents for its long and dependable service, standard quality and modern design. When you are in the market—remember it will pay you to purchase equipment that has won the confidence of leading engineers.



Robb Engineering Works Co., Ltd.

Amherst, N.S.

D. K. McLaren Leather Belting

Belting trouble ends where D. K. McLaren's Belting begins

What Experienced Users Think of D. K. McLaren's Leather Belting is a Sure Guide as to What It Will Do For You!

Get in touch with some of these users. Write us; we'll gladly furnish you with some names and addresses.

No secret is made of the process by which McLaren Leather Belting is made. In fact we wish everyone to know the quality of each feature.

The Hide. The hides are cut from the **backs** of the choicest steers. The back is the strongest part and of even strength and elasticity throughout.

The Tanning. The genuine British Oak Tanning Process gives McLaren's Belting that mighty toughness. No better method is known for treating leather for belts.

The value of these two features is apparent the moment the belting is installed. Slipping reduced to a minimum, thus saving considerable power, and lack of stretch—these are the results.

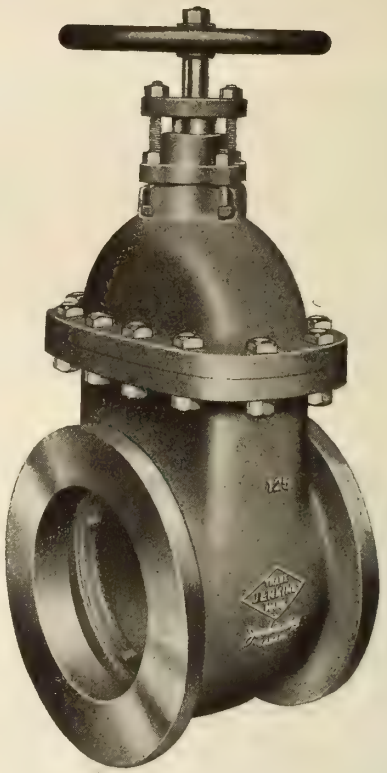
A DEPENDABLE VALVE FOR EVERY PURPOSE

The Valve Test That Safeguards A 56 Years' Reputation

We might well depend solely upon the care used in their designing and the high-grade materials from which they are made to maintain the high standard of value established by Jenkins Valves some 56 years ago.



—but that our enviable reputation may be preserved unimpaired we see to it that every valve bearing our well-known Diamond Trade-Mark is **thoroughly tested before leaving the plant.**

So that the valve purchaser who specifies Jenkins Valves is insured against the losses inherent with the cheap imitations of the genuine Jenkins, a host of which is now on the market.

Therefore—look for the Diamond Trade-Mark on the body of the valves you buy. It is your guarantee of long and satisfactory service, even where conditions of usage are more than ordinarily severe.

Stocks at all good dealers.

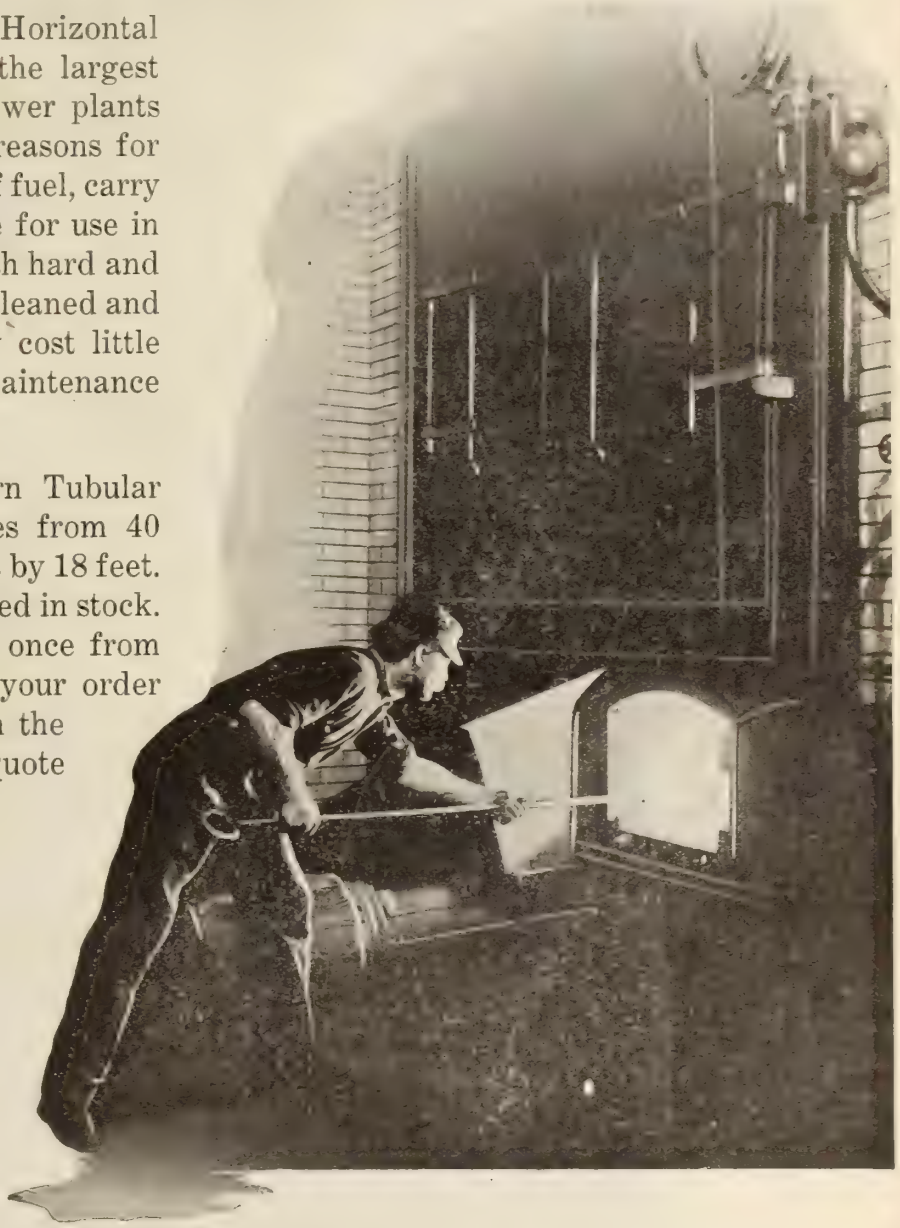
BOILERS

FOR POWER AND HEATING PURPOSES

You will find Waterous Horizontal Return Tubular Boilers in the largest industrial and municipal power plants in the country. There are reasons for this. They are economical of fuel, carry a big reserve steam pressure for use in emergencies, can be used with hard and dirty water, and are readily cleaned and easily taken care of. They cost little new; their upkeep and maintenance expense is negligible.

Waterous Horizontal Return Tubular Boilers are built in all sizes from 40 inches by 10 feet to 72 inches by 18 feet. Most standard sizes are carried in stock. If we cannot supply you at once from our yards we can turn out your order for you in quick time. On the next boiler you need let us quote you prices and delivery.



Boilers in Stock

1—54 x 14 Horizontal
2—60 x 14 "
4—66 x 16 "
14—72 x 18 "
2—40 H. P. Locomotive

Waterous

BRANTFORD, ONTARIO, CANADA

POWER HOUSE. September 5, 1920. Vol. XIII., No. 17. Published semi-monthly at 143-153 University Ave., Toronto, Canada. Subscription price in Canada, $2; in United States, $2.50. Entered as second-class matter at the Post Office Department, Ottawa, Canada. Entered as second-class matter July 1, 1912, at the Post Office at Buffalo, under the Act of March 3rd, 1879.

A Simple Thoroughly Tested Vacuum Pump

Every Nash Hytor Vacuum Pump is carefully tested as to capacity, vacuum and horsepower before it leaves the factory. These pumps are manufactured on the limit system, with Johansson measuring blocks as a reference. Interchangeability of all parts is assured.

Nash Hytor Vacuum Pumps have only one moving part—the rotor, and it is supported on a very heavy, carefully proportioned shaft. All valves, sliding vanes, pistons, gears, crank shafts, cams and rubbing surfaces are eliminated.

The fact that the Nash Hytor Pumps are in extensive use in many of the largest engineering plants is evidence of their superiority.

If you are interested in learning more about the many valuable features of these pumps, write us. **Send for Bulletin No. 11.**

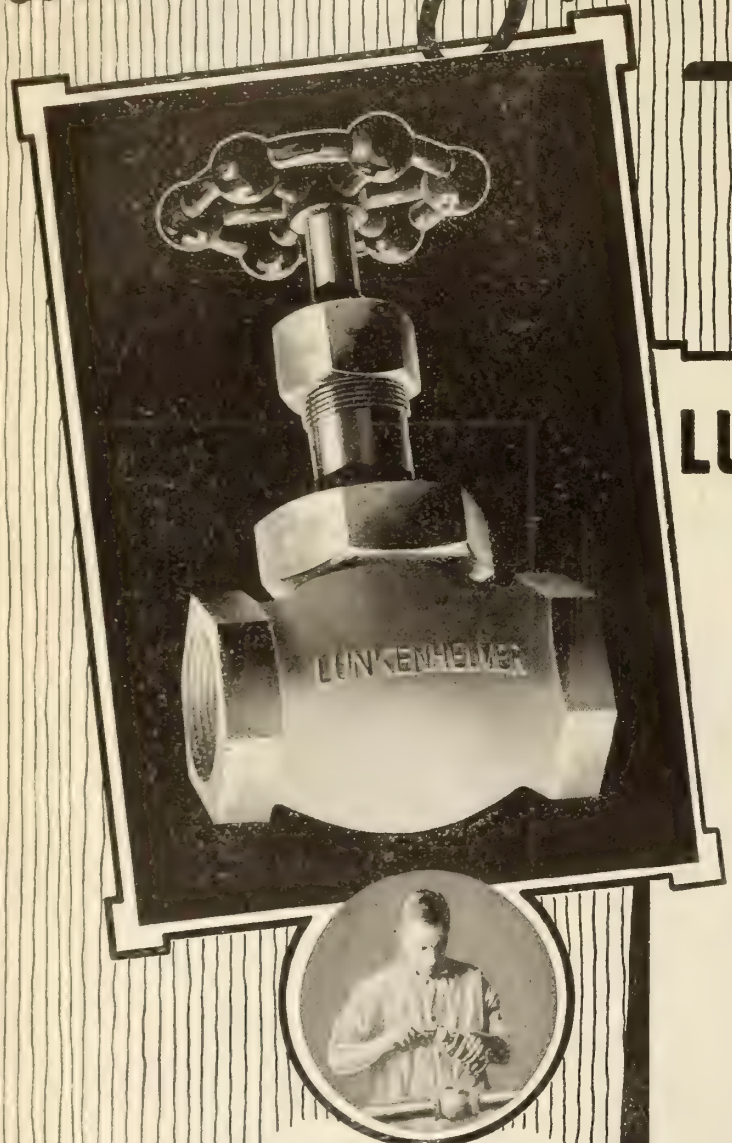
Superiority—unfailing performance—service



The original Regrinding Valve

AMERICA'S BEST
LUNKENHEIMER
"QUALITY"
SINCE 1862

LUNKENHEIMER REGRINDING VALVES

have firmly established their unparalleled merit by the successful results they have given through many years of satisfactory service.

The metal to metal seat—ground to a tight fit, forms the ideal seating surface to resist the wearing action of steam at high velocity. And the fact that the seating surfaces can be reground (an inexpensive operation easily accomplished) makes the renewal of parts wholly unnecessary.

Their extreme durability due to correctly proportioned parts, high quality materials and expert workmanship insures economy in maintenance.

Globe, Angle and Cross Valves with Inside Screw and with Outside Screw and Yoke; and Horizontal, Angle, Vertical and Swing-Check Valves for 200 and 300 pounds working steam pressure.

Specify **Lunkenheimer** and insist on their installation. Distributors of Lunkenheimer Products situated in every commercial centre.

New Truths and Old Fallacies

Fusibility of Alloys—*Continued*

All intermediate grades of babbitts have the same fatal defect of low fusibility, as indicated below by figures of test made by the American Society for Testing Materials, and these figures apply as well to any composition that can be made within these limits:

Tin per cent.	Antimony per cent.	Lead per cent.	Copper per cent.	Melting point
78	12	10	3	365° "
65	15	18	2	365° "
20	15	63½	1½	365° "

The melting point of these quaternary alloys is lower than those of binary or trinary alloys.

It is a common occurrence for technically educated men, holding high positions in railroad and commercial concerns, to adopt and publish as their standards, babbitt alloys of these low melting points. Very likely certain tests were undertaken before a decision was made, or they may have taken the word of some alleged expert, but the fact remains, nevertheless, that either Genuine Babbitt or the right grade of lead base babbitt would have given better and more economical service than these other mixtures, and this they could have discovered had they made the proper comparative tests and carried them to a definite determination.

In cases where thin, loose shell bearings are used and malleability is paramount to all other considerations, the use of Genuine is warranted; but in all other cases where the lining is anchored to the shell by recesses or soldering, a good lead base metal will give, by far, the best service, and this also applies to many patterns of bushings.

Pratt & Cady Valves Built For Lasting Service

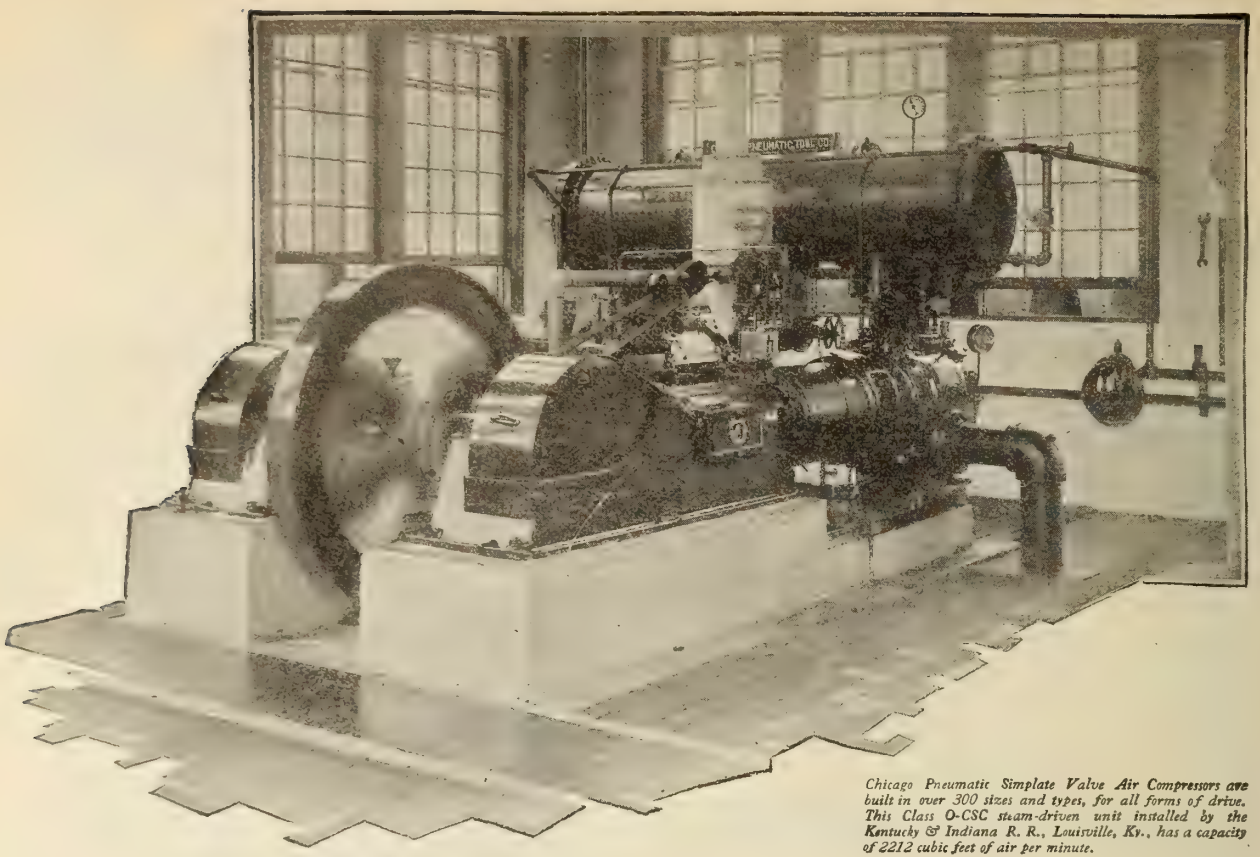
Almost half a century ago we started to build valves in a little shop that would seem insignificant to-day. But though our quarters were small our ideas were big. Also our ideals.
Correct design, high grade materials, conscientious workmanship—these were the slogans of our early days. As the result of adherence to our ideals we often come across a Pratt & Cady valve that has been in service for an amazing stretch of time—practically as good as new.
Throughout the long years there has been no drop in our standards. In 1920, just the same as a generation ago, the P & C Trade Mark is your assurance of the right goods that stands for lasting service.

Write for booklet

BOSTON CHICAGO CLEVELAND DETROIT HARTFORD

PRATT & CADY CO., INC.

NEW YORK PHILADELPHIA PITTSBURGH ROCHESTER SAN FRANCISCO



Chicago Pneumatic Simplate Valve Air Compressors are built in over 300 sizes and types, for all forms of drive. This Class O-CSC steam-driven unit installed by the Kentucky & Indiana R. R., Louisville, Ky., has a capacity of 2212 cubic feet of air per minute.

Another way in which Chicago Pneumatics save power

FROM no-load to full-load, Chicago Pneumatic Air Compressors economize power.

Under all load conditions the cylinder ratio of stage machines is unchanged. This insures highest power economy under variable air demands.

Under no load the inlet valves are automatically held open, permitting free passage of air.

Chicago Pneumatics thus save power over those compressors using a "choked intake" with its resultant losses.

Bulletin 400 tells about this and other Chicago Pneumatic economy features. May we send your copy?

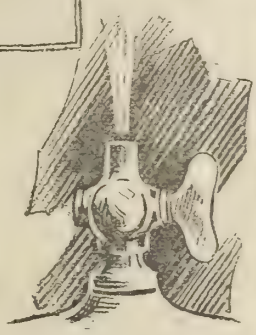
Pet Cocks and Steam Traps

WHEN used as indicators of how a steam trap is operating pet cocks are all right. But, as outlets for air and steam, pet cocks often waste more than the actual cost of the steam trap.

Johns-Manville Steam Traps discharge air through their discharge outlet as well as water and without the loss of steam.

1. *Pet cock discharges water: —indicates that trap is not operating properly due to overload or obstruction.*



2. *Pet cock discharges air: —indicates trap is full of air, which if not discharged will air-bind trap and system.*

3. *Pet cock discharges steam:—indicates trap is properly discharging all air and water and that system is clear.*

A little leak that costs a lot

This partially open pet cock is an inefficient remedy for "trap air binding"—it provides an outlet for air which the trap will not discharge, but allows steam to continually leak out and be wasted.

Note—At 100 lbs. pressure a round hole only 1/32" in diameter will allow about 40,800 lbs. of steam to escape every year—an approximate waste of $19 00 worth of coal.

POWER PLANT MATERIALS

For Outside Drives—
KLINGTITE—an All-Weather Belt

The service given on outside drives by Goodyear Klingtite Belting (formerly Extra Power) is unusual enough to be of interest to every belt user.

Not because there are a great number of outside drives—but because the outside drive is just about the ultimate test of a belt's ability.

The specially designed fabric of Goodyear Belting gives it the strength to withstand brutal outside service.

But the best of cotton will rot and whip to pieces outdoors if not protected.

So we have forced generous quantities of high-grade rubber through and through the plies of Goodyear Klingtite Belting, forming one solid unit, proof against weather and ply separation, yet flexible, pulley-hugging, efficient.

The special friction surface on Goodyear Klingtite Belts (formerly Extra Power) grips through dust or moisture and prevents slipping.

How well these belts serve is evidenced by this letter from the Beaver River Lumber Co. regarding their Extra Power Belt (now Klingtite). At last report (June, 1920) *this belt was still in service after 32 months' use,* when this mill was burned recently.

In their letter the Beaver River Lumber Co. say: "The belt driving the conveyor runs direct from a small engine to the conveyor drive. It is subject to steam and heat in the engine room and to cold and dampness on the outside. Under these conditions, there is no sign of deterioration and there is no slippage."

The same testimony is advanced by hundreds of farmers and threshermen who bought Goodyear Klingtite Belts (under their old name of Extra Power) for severe outside service on the farm.

If you have an outside drive, by all means investigate Goodyear Klingtite Belts. If you have *any* transmission drive, let a Goodyear Belting man show you how Goodyear Belts, which are good enough for outside service, will render heaping value on inside work. Phone, wire or write the nearest Goodyear Branch and a man will call without obligation to you.

"Taking a Chance" Is Speculation— Not Business

YOU do not have to speculate when you buy insulation. The facts are all available and will be furnished you —the records of Nonpareil Corkboard for 20 years.

Get the facts—or better still, investigate for yourself any installation of Nonpareil Corkboard, preferably an old one. Find out whether it is still holding temperatures as well as when new. Is it wet? Has it decayed? Has it any odor? Do the owners feel that they got their money's worth and more? Then go after other insulating materials the same way. Compare results and decide on a business basis—with all the facts.

Ice storage, New State Ice Company, Oklahoma City, Oklahoma, insulated with mastic finish Nonpareil Corkboard.

Nonpareil Corkboard meets every insulation requirement and has been doing it for years. It is a known quantity. You can be *certain* of what it is and what to expect of it. "Why take a chance?"

To get the truth of insulating problems, write for "Nonpariel Corkboard Insulation," a book of real facts, which will be sent without charge on receipt of your request.

ARMSTRONG CORK & INSULATION COMPANY, 504 McGILL BUILDING, MONTREAL, QUEBEC, CANADA

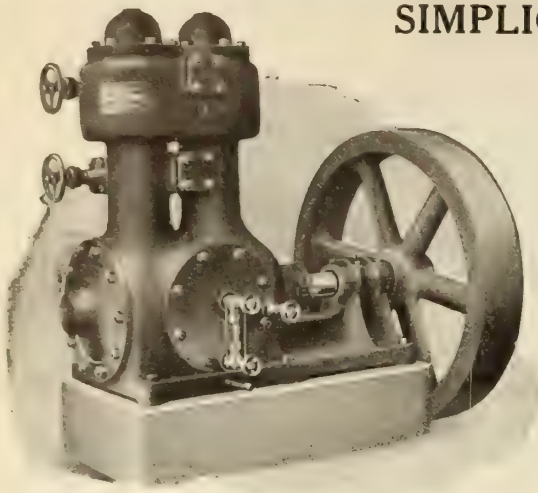
Also manufacturers of Nonpareil Cork Covering for cold pipes; Nonpareil High Pressure Covering for steam lines; Nonpareil Insulating Brick for boiler settings; Nonpareil Cork Machinery Insulation for deadening the noise of machinery; Circle A Cork Brick for cold storage room floors; and Linotile for office floors, residences, etc.

Nonpareil Corkboard Insulation

For All Cold Storage Rooms

York Enclosed Refrigerating Machines

SIMPLICITY—ECONOMY



After operating one of our Enclosed Machines for several years, one of our customers writes us that he has not spent one cent on it except for oil, and is still using the original charge of ammonia. This is a common experience among users of these Machines.

Simplicity of design and accuracy of construction permit them to be operated successfully by employees who, prior to the installation of these machines, never had any experience in operating one.

If you are finding the present scarcity of ice a burden to your business here is a simple and safe method of relief, and besides MECHANICAL REFRIGERATION pays good dividends on the investment.

Write us for information and prices.

In the LARGEST and MOST MODERN PLANT in the WORLD, building Insulated DOORS and allied products exclusively, we are building what we KNOW to be THE BEST INVESTMENT FOR THE USER and the universally recognized WORLD'S STANDARD DOORS. In verification:—

THE HARRIS ABATTOIR CO., Ltd., Canada.

"Our Coolers and Freezers are mostly equipped with your doors. In fact we adopted it as Standard throughout our plant, as we find them substantially made and the insulation perfect. We also find the Hardware stands up better than on any other door we have seen or tried."

LOUISVILLE SOAP CO., Louisville, Ky.

"Coolers at one of our plants are equipped with your doors, which have given us such satisfaction we wish to improve the doors at our old plant. We would not be warranted in throwing out the doors but would like the type hardware you supply."

THE WASHINGTON MARKET, Washington, D.C.

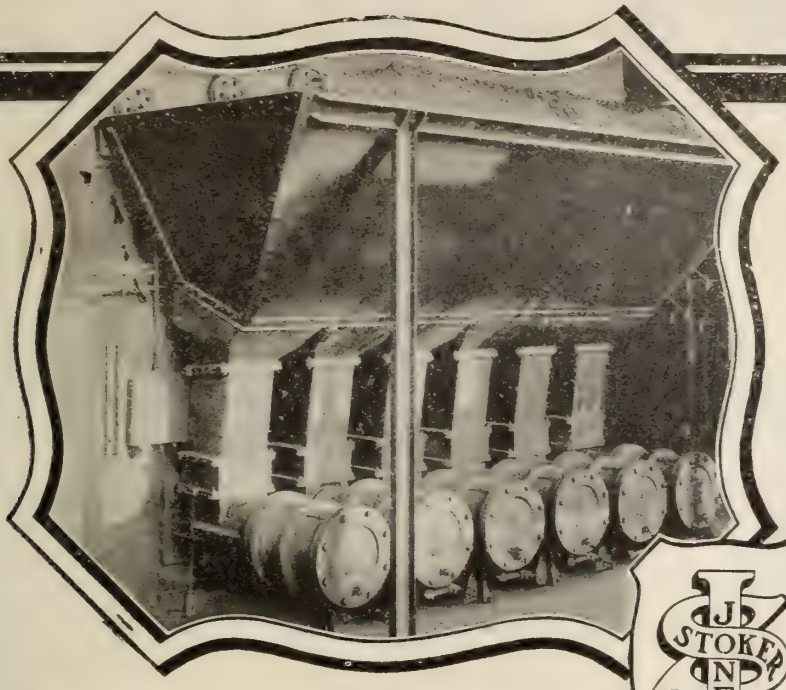
"The doors supplied by you, in use at both plants, have been in every way satisfactory, and we thing the Jamison door is the best on the market."

Read 'em again, men—analyze them! Acquaint yourself fully with our method of construction through latest catalog No. 9—just off the press.

Jamison Cold Storage Door Company

Formerly Jones Cold Store Door Co. HAGERSTOWN, MD., U.S.A.

Jones "A-C" (Automatic-Cleaning) Stoker



Interior and exterior of new power house equipped with Jones "A-C" Stokers.

Saves Coal

—The Big Item in Present-Day Production Costs

The Jones "A-C" is a high-duty stoker, not only in name, but in service. It will operate more efficiently and cost less per ton of coal burned because it fulfills a rigid set of requirements met by no other mechanical stoker.

Overload Capacity—Operated at highest boiler capacity for indefinite periods.

Fuel Economy—The under-feed principle of combustion (originated by this company) insures highest efficiency with any grade of coal. The automatic control of fuel and air, the automatic cleaning feature and the mechanical movement of the fuel bed are factors which combine to insure greatest economy of fuel.

Continuous Operation—The rugged simplicity means little or no shut-downs for repairs—lowest maintenance. Prevention of clinker formations on side walls and "automatic-cleaning" eliminates cleaning of fires which, in most stokers, causes slumps in boiler capacity.

Lowest Labor Costs—Operation is so completely automatic that one man can easily tend several boilers.

The extensive "A-C" catalog explains the many economic advantages of installing a real high-duty stoker.

THE STOWE STOKER

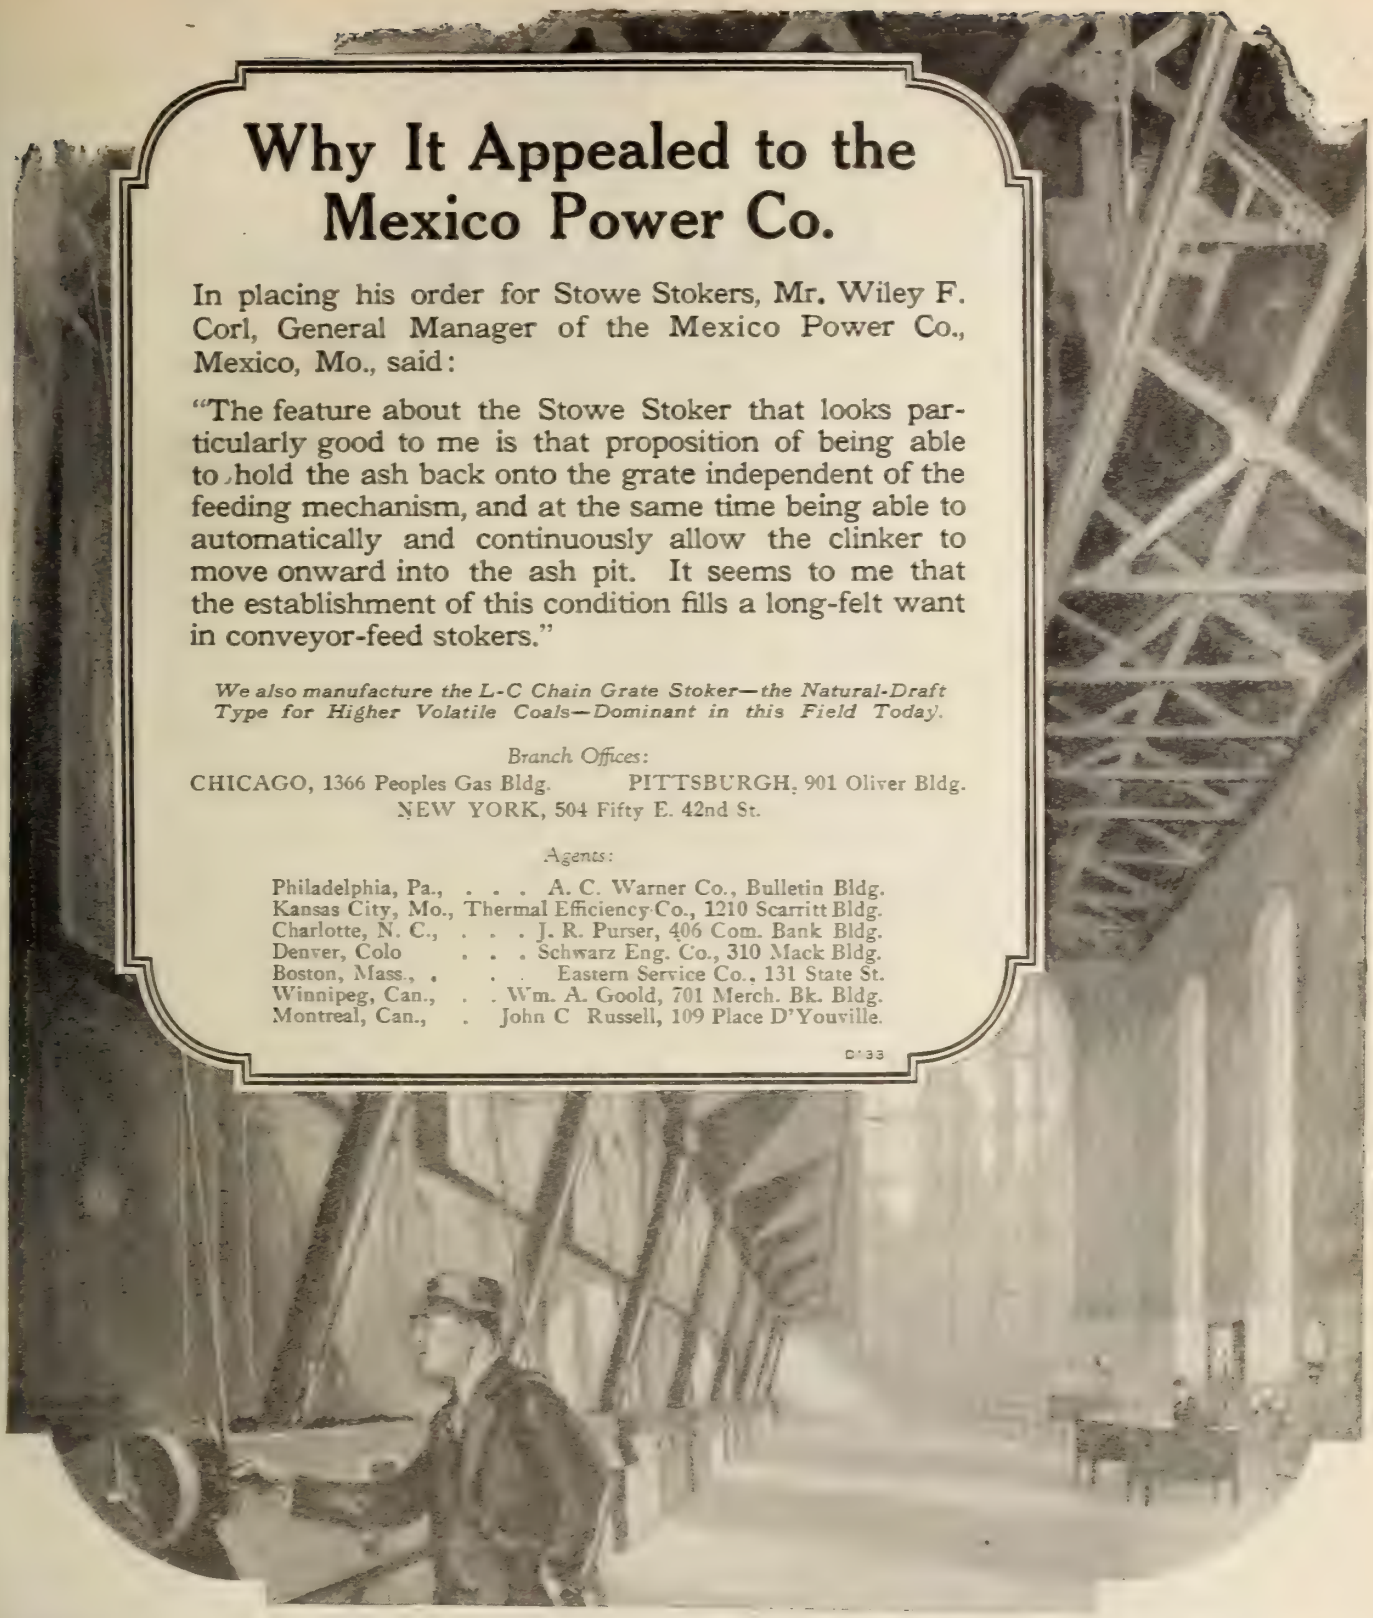
EMPLOYING MECHANICAL DRAFT

Its fundamental principle is a conveyor-feed, positive in action from coal-hopper to ash-pit.

MEXICO POWER CO., MEXICO, MO.

LACLEDE

A BUSINESS INSTITUTION



Why It Appealed to the Mexico Power Co.

In placing his order for Stowe Stokers, Mr. Wiley F. Corl, General Manager of the Mexico Power Co., Mexico, Mo., said:

"The feature about the Stowe Stoker that looks particularly good to me is that proposition of being able to hold the ash back onto the grate independent of the feeding mechanism, and at the same time being able to automatically and continuously allow the clinker to move onward into the ash pit. It seems to me that the establishment of this condition fills a long-felt want in conveyor-feed stokers."

We also manufacture the L-C Chain Grate Stoker—the Natural-Draft Type for Higher Volatile Coals—Dominant in this Field Today.

A Series of Articles on Power Plant Management

This Article Deals with Boiler Feed Water Heaters, the Merits of the Open and Closed Types Being Compared.

By ROBERT JUNE

THE gradual development in the use of pulverized coal in this country had its inception some thirty years ago in the application of this type of fuel to the production of cement. From cement furnaces its use gradually spread to metallurgical furnaces. Marked economies have been effected by its use in these fields, with the result that it is now being successfully applied to a great many types of furnaces, such as forging, continuous heating, busheling, puddling, and open hearth.

It is estimated that ten million tons of coal are burned in the United States annually in this manner. Its use, therefore, is not new, nor is its equipment in an undeveloped state.

This fact is of considerable importance in considering one of the newer aspects of the use of pulverized coal—that is, its application to steam boilers. The problem has been principally that of adapting processes and equipment, already well developed, to the peculiar needs of the boiler room. The incentive has been that of lowering the cost of power production. Owing to factors which will be discussed, the problem of lowering the cost of power production by means of pulverizing coal has not proven readily capable of solution. Power costs have been lowered in a great many cases, and the increasing cost of coal, together with the opportunities which pulverizing offers to use lower grades of coal, makes its wider application in the power field a certain event of the future.

Possibilities of Burning Lower Grade Coals

Practically any coal can be burned in pulverized form with a proper furnace and burner equipment. This means that coals from which very inefficient results have heretofore been obtained, can be brought within the reach of a great many consumers. For instance: the Western country from Texas to Alberta is underlaid with various grades of lignites, low grades of mineral coals with high moisture content, fuels of such a nature that the ash would melt or flow down on the grates if burned in the usual manner. The nature of these coals is such that they do not behave satisfactorily as gas producers. Consequently pulverizing offers unusual opportunities to burn these coals efficiently.

The following analyses are typical of these low-grade Western coals which may be burned in pulverized form:

Kind of coal	Fixed Carbon	Volatile	Ash	Moisture	B.t.u.
Mineral	45.22	26.39	20.38	8.01	10,940
McAlester ..	47.07	32.37	14.29	6.27	11,837
Lehigh	41.40	31.28	19.29	8.03	11,200
Lignite	25.50	33.95	7.58	32.97	7,548

The sulphur, separately determined, ranged from approximately 3 to 5 per cent. in the various soft coals.

There are, around the average steel mill, large quantities of waste fuel such as coke breeze. This fuel is being used to a certain extent on some forms of grates, with forced draft, but it can be burned to very much greater advantage in pulverized form. Another possible use for this method of combustion is in the anthracite field, where there are large quantities of coal in the form of dust and fine particles which accumulate as a result of washing and crushing operations, and which are then pumped back into the mines to fill up the old workings.

We do well to refer to the possibilities of burning low-grade coals in order to emphasize the wide application of the pulverizing process, but you must remember that its application is not necessarily limited to low-grade coals, but that there is a very real possibility that the process can be used advantageously in competition with stokers for high-grade coals.

What is Pulverized Coal?

Pulverized coal is not coal ground to powder. Pulverized coal, to be considered as such, must be properly dried, crushed, and pulverized so that the product contains a very high percentage of impalpable powder. To be satisfactorily burned by this process the coal must be ground so fine that at least 95 per cent. will pass through a 100-mesh screen, that is, a screen having 10,000 openings to the square inch, and at least 85 per cent. must pass through a 200-mesh screen, that is, a screen having 40,000 openings to the square inch.

The finer the coal is pulverized the more effectively will it be diffused when mixed with the air for combustion, and the higher will be its efficiency in the furnace.

When a cubic inch of coal is pulverized so that 95 per cent. passes through a 100-mesh screen, we have divided it into some 200,000,000 particles. Our original cubic inch of coal has a superficial area of 6 square inches, whereas the combined areas of this multitude of small particles is approximately 30 square feet, an increase of 700 times in exposed area. It is this exposed surface which permits perfect and instantaneous combustion.

Advantages and Disadvantages

Among the advantages of pulverized coal are the following:

1. Permits much wider variation in the quality of coal. The adaptability of stokers is limited. A stoker designed for one grade coal will not handle all other grades effectively. Pulverizing is of considerable advantage, therefore, where there are frequent variations in the grades of coal, or where much coal of low quality is encountered.

2. The pulverizing system is very flexible, permitting of very rapid increases of load. In this characteristic, pulverized coal resembles oil and natural gas.

3. Standby losses can be very materially reduced. By taking the load off the boiler, shutting off the fuel, and closing up the furnace, a condition of incandescence can be maintained with the boiler pressure practically up to normal, for a period of hours. By throwing a switch, the entire firing operation can be stopped, an advantage in case of accident or emergency.

4. In stokers the amount of coal that can be burned per square foot of grate area is limited, so that for increased capacity the boiler setting must be spread out to cover greater area. In using pulverized coal this condition does not exist, for proper furnace conditions can be obtained by increasing the height

5. Ash is easily handled. Being in the form of a dust or slag, it is readily removed. This fact makes it easy to

maintain constant furnace temperatures as there is no interference with firing conditions on account of cleaning fires.

6. There is no trouble with clinkering on the grates.

7. Pulverized coal as fired contains less than 1 per cent. of moisture, whereas with ordinary methods of firing, coal may contain from 1 to 10 per cent. of moisture.

8. Considerably less excess air is required for combustion. This is a point of the greatest importance. In this respect pulverized coal compares with fuel oil. The less excess air we have, the smaller volume of mechanical draft required, and the smaller the stack losses.

Among the disadvantages of pulverized coal are:

1. Cost of preparation.
2. Explosibility of coal dust.
3. Limitations of storage.
4. Depreciation of furnace linings
5. Discharge of large amounts of refuse through chimney.

Pulverized Fuel Equipment

A pulverizing plant consists of the following principal units: crusher, crushed coal dryer, pulverizer, storage and conveying apparatus, and burners. The size of the plant will determine the number of each of these various units to be employed.

In a typical installation the coal is dumped by gravity into a track hopper from which it is taken by a belt conveyor to a hopper located above the coal crusher. Magnetic separator pulleys are located between the track hopper and the crusher hopper to remove scrap metal, such as bolts, pick points, etc. After being crushed to about 1 in. in diameter the coal drops to an elevator pit, from whence it is taken by the elevator to the dryer storage bin.

The coal dryer is cylindrical in form, being rotated by a small motor, or by a pulley from a line shaft. It is usually heated by hand firing on grates. It must necessarily be of such a size to deliver the entire quantity of coal, thoroughly dried, for continuous operation of the power plant.

From the dryer the coal again falls into an elevator pit, from whence it is carried to the pulverizer hopper. In this process it is again carried over a magnetic separator pulley to remove any small pieces of metal which may not have been caught by the first magnet. By stops and gates the coal is fed to the pulverizer, which grinds it to the required fineness. From the pulverizer the coal is conveyed by screw conveyor or air pressure to the storage bins. The capacity of these bins must be determined with reference to the service required, bearing in mind that provision must be made for periods when the pulverizers may be out of commission.

Crushing Rolls

There are a number of good standard makes of crusher rolls on the market. That illustrated herewith is the Jeffrey (Fig. 1). The rolls are equipped with [illegible] springs and breaking shells are provided which permit them to separate under excessive strain. The crushing surface consists of segmental toothed or corrugated sections secured to a hexagonal drum, so that broken or worn-out sections can be replaced without renewing the entire roll.

Coal Dryer

Fig. 2 illustrates the Fuller-Lehigh indirect firing rotary coal dryer, which consists of an axially inclined cylindrical shell fitted with suitable rollers and

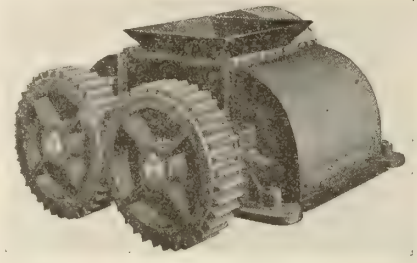

FIG. 1—COAL CRUSHER.

gearing to permit the shell being rotated on its longitudinal axis. The higher end of the dryer shell terminates in a brick housing which serves to support the stack required to discharge the waste products of combustion of the dryer furnace, and the vapor given off by the moist coal being dried. The lower end of the shell terminates in a steel hood. The furnace for heating the dryer is placed between the stack chamber and the hood. This furnace may be provided with one or two fireplaces, depending upon the size of the dryer. The furnace is provided with a large combustion chamber through which the dryer shell passes. The entire furnace is built of brick and the walls are securely bound together by means of buckstays and tie rods.

The moist coal is fed into the dryer shell through a feed spout located in the stack chamber. This spout enters the dryer shell and delivers the coal close to the bottom of the shell. A series of longitudinal shelves fastened to the inside of the dryer shell lifts the coal and drops it through the current of heated air passing through the inside of the dryer shell. Inasmuch as the revolving shell of the dryer is slightly inclined downward toward the discharge end, the coal travels the entire length of the shell and is finally discharged, perfectly dried, from the lower end of the dryer shell.

The hot gases from the furnace fire circulate around the outside of the dryer shell, passing through the combustion chamber of the furnace. They then leave the combustion chamber through the horizontal breeching and enter the top of the hood at the lower end of the dryer. From this hood the hot gases flow to the interior of the dryer shell, and come in direct contact with the coal in the dryer shell. After they pass through the interior of the dryer shell the hot gases enter the stack chamber at the upper end of the dryer and then escape to the atmosphere through the stack.

The Pulverizer

Pulverizing mills may be either the ball or the roller type. In the ball type illustrated herewith (Fig. 3) the material to be reduced is fed to the mill from an overhead bin by means of a screw feeder. The feeder is driven from the mill shaft by a belt running on a pair of three-step cones, thus permitting the operator to regulate the amount of material entering the pulverizer. The pulverizing elements consist of four large steel balls, rolling in a stationary, horizontal, concave, grinding ring. Material discharged by the feeder rails between the ball and the grinding ring in a uniform and continuous stream, and is reduced to the required fineness in one operation. Material is drawn through screens and discharged by means of fans.

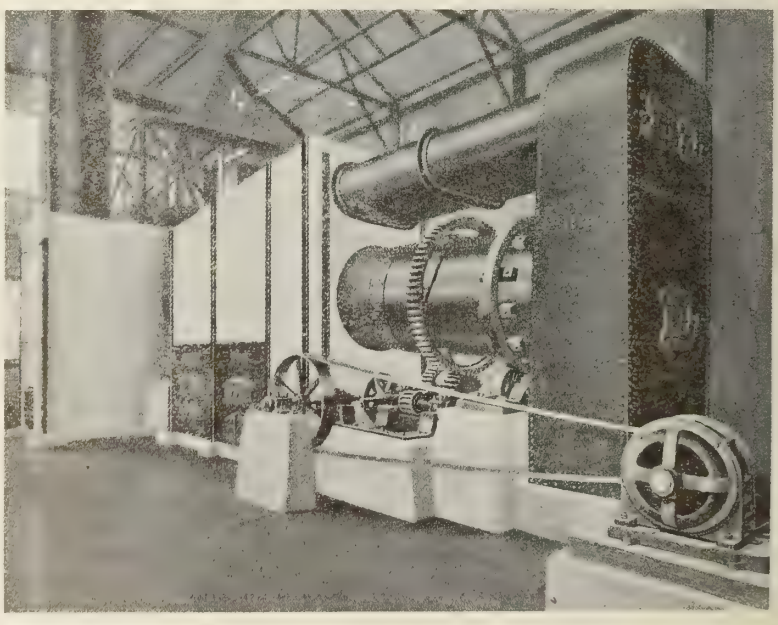

FIG. 2—COAL DRYER.

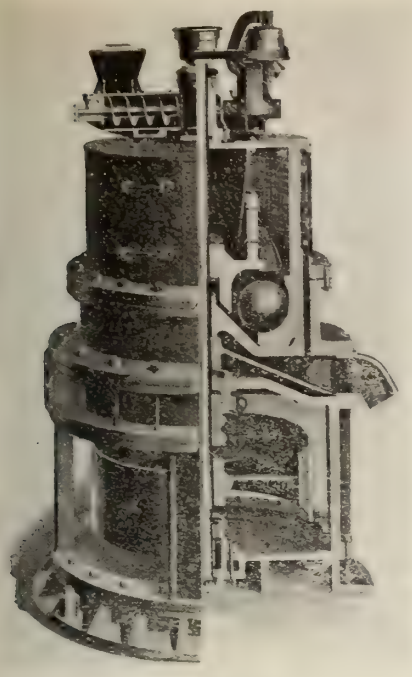

COAL PULVERIZER.

Feeders, Mixers and Burners

Figs. 4 and 5 illustrate the "Lopulco" feeders and burners. The functions and methods of operation will be evident from the illustrations. The essential requirements of pulverized fuel feeders and burners are:

1. Positive control of the fuel feed.
2. No flooding and clogging.
3. Ability to regulate temperature in furnace.
4. Adaptability to various grades of fuel.
5. Control of combustion and length of flame.

Cost of Pulverizing Coal

What does it cost to pulverize coal? Well, the cost of pulverizing is made up of a number of items, as follows:

1. Interest.
2. Depreciation.
3. Insurance and taxes.
4. Repairs and maintenance.
5. Power.
6. Labor.
7. Coal for drying.

Interest. This will depend upon the cost of installation, which is of course

LOPULCO FEEDER.

dependent upon its size and type. Mr. F. A. Scheffler is authority for the statement that, as a general proposition, the actual investment will vary from $12.80 per K.W.—output in a 5,000 K. W. plant, —down to $4.80 per K. W. in a 50,000 K. W. plant. If we assume that the 5,000 K. W. plant uses 100 tons of pulverized coal daily, and that the cost of the plant is approximately $64,000, we have a charge of 10 1-2c per ton for interest. A plant using a thousand tons daily would have its charge reduced to approximately 4c per ton.

Depreciation. If we assume the life of the equipment as ranging from 15 to 20 years, our depreciation in a hundred ton per day plant will be approximately 12c per ton, and in a thousand ton plant, approximately 4c per ton.

Insurance and Taxes. Assuming taxes and interest to amount to 2 per cent. on investment, we have a fixed charge of 3 1-3c per ton for a hundred ton plant, and 1 1-2c per ton for a thousand ton plant.

Repairs and Maintenance. Experience would indicate that repairs and maintenance will run from 10 to 20 cents per ton. This is, of course, a general statement, and there are, no doubt, plants in existence which show a lower cost of repairs. However, it would hardly be safe to figure on any less cost than 10c per ton in estimating the possibilities of a prospective plant.

Power. The power required to operate an up-to-date pulverized coal plant, consisting of crushers, dryer, and pulverizer, and including the transportation of coal from the track to the boilers, may be set down as ranging from 15 to 20 K. W.-hr. per net ton, with 17 or 18 K. W.-hr. as the probable average.

LOPULCO BURNER

If we assume the cost of power to be 3-4c per K. W.-hr., we have a charge of approximately 13c per ton for power.

Labor. This item varies so widely that it is extremely difficult to estimate the cost with any accuracy. For purposes of approximation we may assume that a hundred ton plant will require 40 hours of labor per day, which, at 50c per hour, would be equivalent to a charge of 20c per ton for this item. A thousand ton plant might be operated with 120 hours' labor, which, on the same basis, would amount to 6c per ton.

Coal for Drying. Coal required for drying may be rather closely estimated at 1 1-4 per cent. of the amount of coal heated. At $2.50 per ton for coal, the cost of drying would be 3c per ton, and at $5.00 per ton, the cost of drying would be 6c per ton.

Summing up these various items we have the following approximate costs:

COSTS OF PULVERIZING COAL PER NET TON AT THE ATLANTIC STEEL COMPANY

Table I.—Daily Output 100 Tons Per Day

	Cost Per Ton
Labor	$0.176
Repairs	0.19
Power	0.134
Dryer coal	0.0218
Total cost	$0.5218

Total coal pulverized Jan.-Feb., 1919...5,275 tons

Power —
17.9 kw.-hr. per ton coal pulverized at ¾c... .....5,275 tons

Labor—

1 man 16 hr., at $0.40	$ 6.40
2 men 16 hr., at $0.35	11.20
Daily cost	$17.60

(=$0.22 for 80 tons output, $0.195 for 90 tons, $0.176 for 100 tons).

Dryer coal—Cost of dryer fuel, 2.8c per ton, based on 2.6% moisture.

Coal at $5 per ton, 6 lb. evaporated per lb. of coal burned, or 8.7 lb. per ton of coal pulv.

Repairs—

Total repairs for Jan. and Feb.,	$1,412.16
Credit	409.69
Charged	$1,002.47

(=$0.19 per ton pulverized)

By way of comparison with the above approximate figures, we have the following actual costs of pulverizing a hundred tons per day at the Atlantic Steel Co. The figures given apply for the months of January-February, 1919, and it is, of course, probable that they would be higher today:

	Cost per ton 100-ton plant	Cost per ton 1,000-ton plant
Interest	$0.10½	$ .04
Depreciation	.12	.04
Insurance, taxes	.03 1-3	.01½
Repairs, maintenance	.15	.13
Power	.13	.13
Labor	.20	.06
Coal for drying	.05	.05
Total	$0.78 5-6	$0.43½

Conditions Governing Successful Use of Pulvarized Coal Under Boilers

The conditions governing the successful use of pulverized fuel under boilers are as follows :

1. Fineness of pulverization.
2. Proper design of combustion chamber.
3. Proper air openings.
4. Damper regulation.
5. Clean tubes.

Let us examine these points in order:

Fineness of Pulverization.—This is a factor which was discussed in our first article. It is absolutely essential that 95 per cent. of the pulverized fuel should be fine enough to pass through a 100-mesh screen. If the pulverized coal contains many heavy particles, these will tend to settle at the bottom of the combustion chamber, and will soon form a solid mass which can only be removed by mining operations.

Proper Design of Combustion Chamber.—It is extremely important in considering a pulverized fuel installation to know beforehand the probable rating at which the boilers are to be driven. On this rating depends the size of the combustion chambers. The safe rule is to figure what the maximum rating will be, and to build the combustion chamber to meet this rating. Our combustion chamber should have a capacity equivalent to approximately 50 cu. ft. per lb. of coal burned per minute.

If our combustion chamber is design-

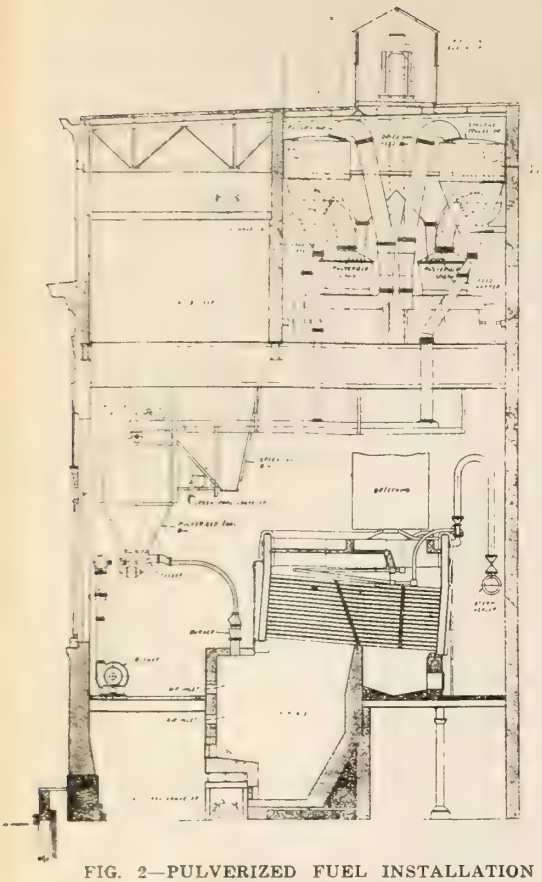

FIG. 2—PULVERIZED FUEL INSTALLATION ONEIDA BOILER PLANT.

ed on this basis, it is important to remember that, if we run the boiler at less than the maximum rating we have determined upon, the efficiency will not be perceptibly lowered. On the other hand if we attempt to run the boiler above the maximum rating, we do not have sufficient combustion space. Hence the flames will impinge on the brickwork and cut it away very rapidly. Furthermore, combustion will not be complete at the time the gases strike the boiler tubes, and there is very great probability that an appreciable proportion of the gases will pass up the stack unburned.

The combustion chamber should also be designed so that the velocity of gases passing through it does not exceed a speed of 6 ft. per second.

Proper Air Openings.—The pressure with which pulverized coal is put into the furnace is as low as can be used and still carry the fine coal in suspension, as the aim is not to blow but to breathe the coal in, and it is usual to find the pressure to be 1-2 oz. at the nozzle.

The importance of this low pressure lies in the necessity of mixing the coal dust and air intimately. Any mixing process that produces such agitation of the coal and air as to give a centrifugal effect will tend to separate and not to mix the materials. We can determine the thoroughness of the mixture by the length of the flame; the poorer the mixture, the longer the flame.

When the powdered coal is fired at high pressure and high velocity, combustion begins at a point 4 to 6 feet from the end of the burner. The action is similar to that of a plumber's blow torch when too much air is used; or in the bunsen burner when the gas pressure is too high. Not only is the combustion slowed down by high pressure firing, but there is a destructive action of the furnace as well. Thus it has been well established that whether oil or gas is used as a fuel, a blow torch effect due to firing or high pressure is always destructive to brickwork.

With powdered fuel this destructive action is increased since, in addition to the eroding effect of the gases at high velocity, there is a fluxing action by the melted ash.

Since our air pressure must be low, we must get the air required for combustion through additional openings. These openings, which are adjustable, are placed at the front, sides and bottom of the combustion chamber. Given openings in these locations, the fireman can, with a little experience, completely control the process of combustion.

Damper Regulation. Very accurate damper regulation is absolutely essential to the successful use of pulverized fuel, as only in this manner can we control the velocities of the gases passing through the combustion chamber. Damper regulation should provide for what will amount to balanced draft inside the combustion chamber, and to only a slight vacuum in the first pass, while at the damper itself we do not want more than .1 to .15 inches. If we have more vacuum than this it pulls our gases through the combustion chamber too fast, thus allowing them to reach the first row of tubes too fast, and causing the deposits to build up on these tubes very rapidly. The very small draft necessary at base of stack will allow us to use pulverized coal with stacks about 30-35 feet in height.

Clean tubes. If you want to attain high boiler efficiency you must keep your boiler tubes clean. This axiom applies to every boiler regardless of fuel used, whether ordinary lump coal, oil, or pulverized fuel is burned. This means that mechanical soot blowers are just as important, just as necessary, with pulverized fuel as with other types. As a matter of fact, in practically all successful installations where pulverized fuel is used, the boilers are equipped with mechanical soot blowers. The tubes should be cleaned by the blowers every 6 hours or oftener. As the temperatures are very high, the blowers should be constructed of some such material as calorized metal in order to withstand the hard service conditions. The regular use of mechanical soot blowers will save 4 to 8 per cent. of fuel, as well as a large amount of the labor required for cleaning.

Boiler Efficiency With Pulverized Coal

It has been said that a comparison of a number of tests of hand fired and pulverized coal furnaces shows a decided gain in efficiency of pulverized coal over the hand fired, where the fuel is of a low grade. The gain is said to become less marked with fuels of fair quality, and to disappear entirely with good coal and properly manipulated stokers. Tests of powdered coal installations are available showing boiler efficiencies of 77 to 81 per cent., but these results have, of course, been equalled with mechanical stokers. As a general proposition, however, we may assume that the average boiler efficiency with pulverized coal is higher than the average with stokers.

As indicating the results which may be obtained with pulverized coal, first in using low grade coals, and then in using coal of fair quality, we give herewith reports of two tests, one on eight 250 h.p. O'Brien boilers at the M. K. & T. railroad shop plant, at Parsons, Kansas; the other on five Edge Moor boilers at the Oneida street station of the Milwaukee Electric Railway & Light Company:

The M. K. & T. Test

With Texas lignite and an output of 110 per cent. rating, an equivalent evaporation of 7.26 lb. of water was obtained per lb. of coal fired, an equivalent evaporation of 8.81 lb. being obtained per lb. of combustible. The coal as fired had a heating value of 11,250 b.t.u. and contained 7 per cent. moisture, the dryer not being designed to handle this class of fuel regularly. The efficiency of the

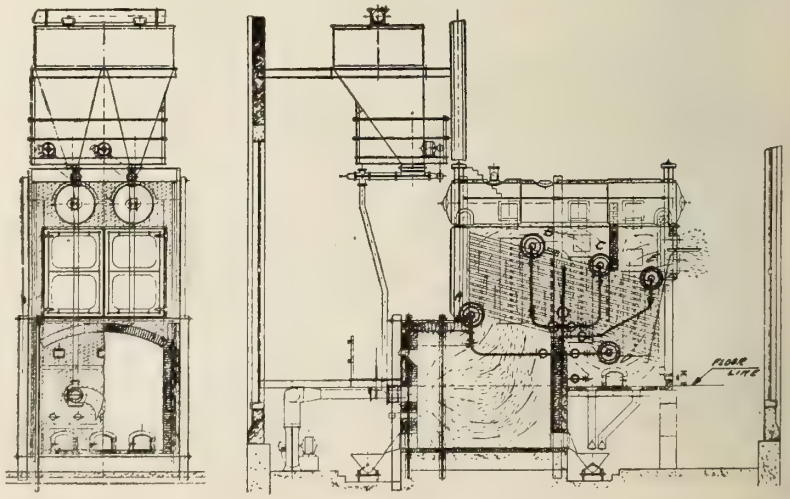

FIG. 1—TYPICAL PULVERIZED FUEL INSTALLATION SHOWING LOCATION OF SOOT BLOWER UNITS.

boiler was 67.3 per cent., the losses being as follows: 7 per cent. due to evaporation of moisture in the coal; 4.8 per cent. due to steam from hydrogen combustion; 11.8 per cent. carried away by dry flue gases, and 15.4 per cent. due to radiation and unaccounted for.

With the boiler operating at about 92 per cent. of rated capacity an equivalent evaporation of 8.38 lb. of water per lb. of coal fired was obtained with Mineral slack (Cherokee Co., Kansas), the fuel as fired containing one per cent. of moisture and having a heating value of 11,580 B.t.u. The equivalent evaporation per lb. of combustible was 10.9 lb. In this case the boiler showed an efficiency of 71.5 per cent., the losses being: .3 per cent., due to evaporation of moisture in the coal, 3.8 per cent. due to evaporation of moisture in the coal, 3.8 per cent. due to steam from hydrogen combustion; 10.8 per cent. in dry flue gases, and 13.6 per cent. radiation and unaccounted for. In neither case was there any CO loss.

Including the cost of pulverizing, which is about 35 cents per ton, the cost of Mineral coal delivered to the bins was $1.795. The cost of evaporating 1,000 lbs. of water as determined by this test was 11.6 cents. Using natural gas, the heating value of which is about 940 B.t.u. per cu. ft., the cost of evaporating 1,000 lbs. of water is 16 cents, with gas at 12.5 cents per 1,000 cu. ft.

The normal coal feed is arranged to develop about the rated capacity of the boiler. At maximum feed, however, the boilers may be forced to 142 per cent. of rated capacity. No difficulty has been experienced from abnormal furnace temperatures, which would tend to destroy the furnace walls. Even under forced conditions the furnace temperature does not exceed 2,350 deg. F., and under normal conditions it is about 2,100 deg. F.

The Future of Pulverized Coal

When we pulverize coal we change completely its common characteristics. Pulverized coal is a fuel of extreme flexibility. The amount burned can be varied within wide limits. Furthermore, to the characteristics of a rich fuel, developing a flame like oil or gas, is added a degree of control fully equivalent to, if not exceeding, that obtainable by burning either oil or gas.

Owing to the attitude of labor and the scarcity of securing skilled operatives, it is far more difficult than ever to secure high efficiency and good operation in either hand or stoker firing.

Either manual or stoker firing requires constant watchfulness, and hot, heavy, disagreeable work. As a substitute for these conditions, pulverized coal offers an ease of control such that the equipment can be operated by any intelligent man without much regard to his physical qualifications.

Pulverized coal permits of generally higher efficiencies than are now being obtained, with much less strenuous effort. It is, therefore, to be seriously considered.

THE MILWAUKEE ELECTRIC RY. & LIGHT TEST.

Summary of Results.

	Electric Energy and Fuel Consumption Per Ton of Coal Pulverized.	
1.	Energy consumed by conveyors, crushers, elevators, dryer, blowers and feeders, kw-hr.	5.73
2.	Energy consumed by pulverizer, kw-hr.	16.72
3.	Total energy, kw-hr.	22.45
4.	Coal equivalent at 1.5 lb. per kw-hr., lb.	33.68
5.	Coal consumed in dryer furnace, lb. per ton of fuel dried	25.66
6.	Total coal and equivalent, lb.	59.34

Conclusions can be best drawn from a comparison between pulverized-fuel burning equipment and mechanical stokers such as is given in Table II.

Table II.—Comparative Results with Pulverized Fuel and Underfeed Stoker Per Ton of Coal Burned.

	Pulv. Fuel System	Modern Stoker
Energy consumed by conveyors, crushers, elevators, dryers, fans and feeders, kw-hr.	5.73	10.94
Energy consumed by pulverizer, kw-hr.	16.72	.....
Total energy, kw-hr.	22.45	10.94
Coal equiv. at 1.5 lb. per kw-hr., lb.	33.68	16.41
Coal consumed in dryer furnace, lb.	25.66	.....
Total coal and equivalent, lb.	59.34	15.41
Cost of Fuel Preparation, Firing and Ash Disposal.		
Labor—Coal preparation	$0.143	$0.000
Labor—Firing	0.112	0.140
Labor—Ash removal (in plant)	0.025	0.064
Dryer fuel—coal at $4 per ton	0.051	0.000
Electric energy—coal per kw-hr. at 1.5 lb.	0.068	0.033
Maintenance: Labor at $0.036—material at $0.020, manufacturer's estimate—lubricants at $0.007. Labor at $0.046, material at $0.048, lubricants at $0.002. $0.097.	$0.063.	
Total cost of fuel preparation, firing, ash disposal and maintenance	$0.462	$0.334
Price of coal as purchased per ton	4.000	4.000
Total cost per ton	4.462	4.334
Cost per ton of coal in P.F. system over modern stoker	0.128	.....
Efficiency.		
Actual gross efficiency, per cent.	80.67	76.80
Net efficiency after all incidental costs have been accounted for, per cnt.	72.32	70.88
Difference in favor of pulverized fuel system, per cent.	1.44	.....

The tests were conducted by the engineers of the Milwaukee Electric Railway and Light Co., being directly supervised by Fred Dornbrook, chief engineer of the Commerce Street station, assisted by Messrs. Schubert & Mistele, test engineers. Paul W. Thompson, technical engineer of power plants, Detroit Edison Co., was present throughout the four days as an observer. The test was approved by John Anderson, chief engineer of power plants, for the company.

TRADE ANNOUNCEMENT

The Superheater Company, Limited, has recently been incorporated and will manufacture superheaters for all classes of service in Canada. The company's main office is in the Transportation Building, Montreal, and the manufacturing plant is located at Sherbrooke, Que.

They will manufacture the type of fire-tube superheaters now in general use in the locomotives of all Canadian railways, and also fire-tube superheaters for marine installations, of which there are now over two thousand in daily service.

In the case of water-tube boilers in marine service, the company designs and manufactures the superheater to suit each individual case. This, in fact, applies in all cases, and in particular in the design and construction of superheaters for stationary installation, either water-tube, fire-tube, or separately fired. The conditions are studied in each case with a view to supplying the most economical and effective installation.

The company employs a form of return bend, which is made by a forging process from the metal of the superheater pipes, making an exceptionally strong construction which is proof against high temperature. This form of return bend has also been considerably sought after for use in pipe coils for refrigerating purposes, condensers and other uses.

SOME SPEED

An average speed of a little over 172 miles per hour was made in a recent flight from Rome to Turin by Lieut. Brack-Papa in an A. R. F. biplane constructed by the Fiat Company and equipped with a 750-horsepower twelve cylinder Fiat engine. The machine started from the Mirafiori aerodrome, in the suburbs of Turin, at 11.45 a.m. on April 5, carrying two passengers in addition to the pilot, and landed on the Centocelle ground, just outside Rome, at exactly 2 p.m. The intervening distance of 388 miles was thus covered in two hours fifteen minutes. A few days previously the same machine was officially timed over the Mirafiori aerodrome and found to give an average speed of 161.5 m.p.h. with four passengers and a pilot. In this flight the effects of wind were, of course, eliminated, and the speed attained, we understand, constitutes a world's record.

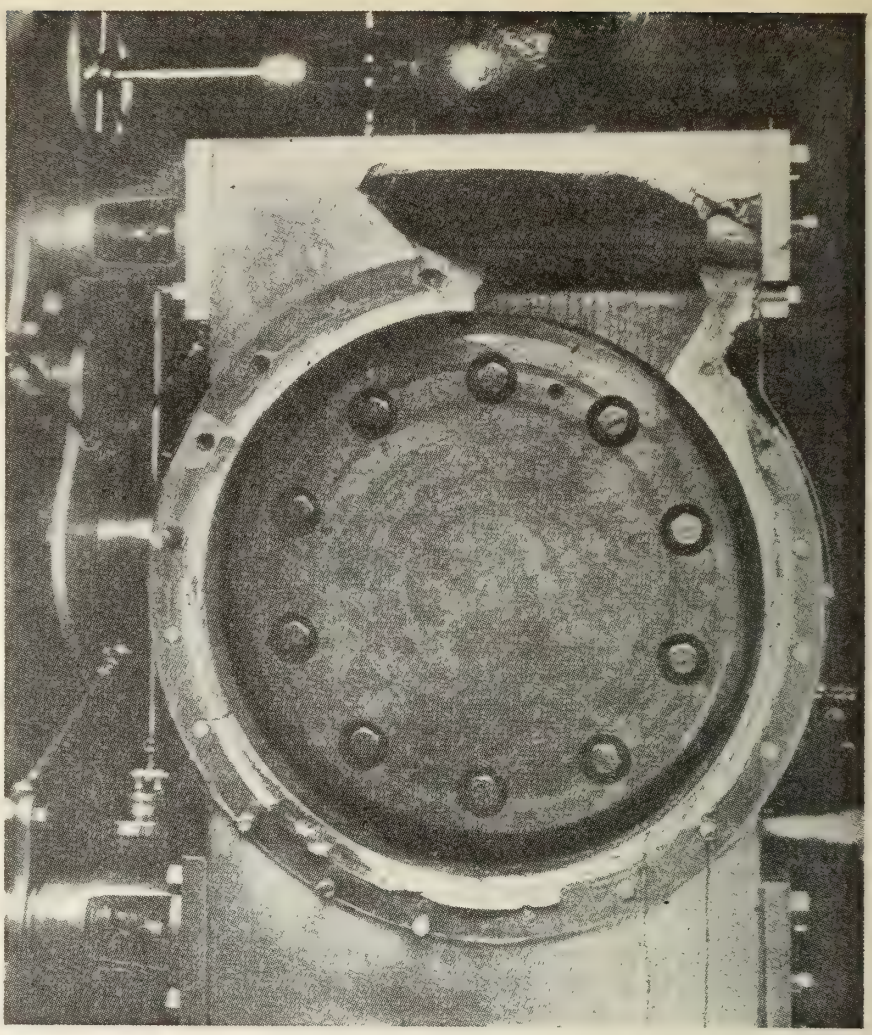
A MYSTERIOUS ENGINE ACCIDENT

THE accompanying illustrations show two views of an accident which occurred not long ago to the steam cylinder of an ammonia compressor. Fortunately no one was injured.

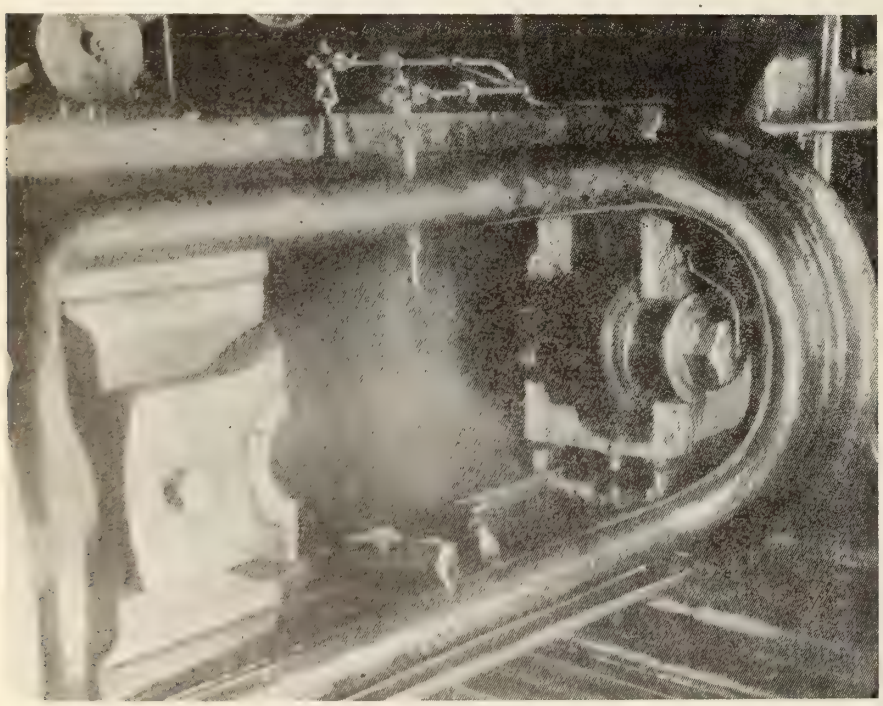
The machine in question consisted of a single horiozntal steam cylinder with two vertical compressor cylinders. The engineer had started this engine up shortly before noon of the day of the accident and, in conjunction with two other ice machines, it had been running smoothly and quietly up to the very instant of the accident. At 4.50 p.m., the engineer passed through the engine room and found everything to be operating to his satisfaction. Five minutes after he left the room the oiler, who was giving his attention to one of the other machines, heard just one crash without the slightest noise or fore-warning of any trouble. He immediately ran to the throttle of the machine and shut off the steam. The engineer arrived soon after and closed the throttle valves on the other two machines.

It was found that the machine had stopped on or very close to the crank end dead center. The cross-head was broken through the wrist pin hole, and apparently it was at this point that failure first took place. A piece of the cross head shoe was found lying on the bottom guide between the two broken parts of the cross-head, which fact might be taken to indicate that the crank-pin had passed dead center and was moving toward the head end when the accident occurred.

When the cross-head failed the steam pressure carried the piston, piston rod and half of the cross head with a high velocity toward the head end of the cylinder. The piston struck the cylinder head, drove it off and the latter was found lying on the floor immediately back of and to the right of the cylinder. The follower plate was cracked circumferentially through the bolt holes for a distance of about thirty inches and the cylinder casting, as is shown in the illustration, was fractured through the steam valve chest. Upon further examination the piston was found to be drawn off the rod, leaving a space of 3-16 in., and on the rod a collar of metal had been rolled up as though the piston had been driven onto the rod. This condition was probably caused by the following series of events: When the cross head failed the steam pressure carried the piston up against the cylinder head which caused it to let go and the cylinder casting to fail as shown. Before the head let go, however, the inertia of the rod and the half of the cross-head attached to it had carried the rod into the piston which caused the collar of metal to be rolled up. The force of these two actions, however, was not sufficient to bring the moving mass to rest so that, after the cylinder head blew out, the parts continued their motion until the nut on the cross-head end of the piston rod brought up against the stuffing box on the crank end of the cylinder. While this brought the rod and cross-head to rest the remaining inertia of the piston caused it to be carried off the rod as mentioned above.



SHOWING BREAK IN CYLINDER.



SHOWING BROKEN CROSSHEAD.

No satisfactory explanation has been given of the cause of this accident. The steam pipes were well drained and the traps found to be in good working order. The firemen reported that the water line in the boilers at the time of the accident was what they were accustomed to call a low one. There does not seem to have been any possibility, therefore, for water to have gotten into the steam cylinder.

The case serves to show that any engine may be subjected at some time to forces of unknown origin which may lead to a more or less severe accident and it furthermore emphasizes the need for engine insurance.

MECHANICAL STOKERS ON AMERICAN LOCOMOTIVES

More than 5100 locomotives on American railways are now fitted with mechanical stokers of six different types, but two of these types aggregate less than 200, while the others range from 500 to 2,195. These figures were given in a report at the annual meeting of the mechanical section of the American Railway Association. Practically all the engines have a tractive effort above 55,000 lb., and in most cases they can haul from 150 to 400 tons more in a train with as good performance as hand-fired engines with the lighter trains.

Although hand firing on large engines is very severe work, few railways employ assistant firemen, but several are using mechanical devices to feed the coal towards the footplate and thus lighten the fireman's work. Higher efficiency and capacity of the large locomotives are the main objects sought in introducing mechanical stokers, but stokers are a practical necessity when coal consumption averages more than 5000 lb. per hour. It is when the full efficiency of the engine cannot be obtained by hand firing that the mechanical stoker begins to show its advantages.

Greater total consumption per trip is the usual experience with machine-fired engines, but it is more than offset by the increased tonnage and load capacity. It is probable also that with further experience the total consumption will be no higher for mechanical than for hand firing. This result will follow from the designing of fire-boxes to suit the conditions of stoker firing and from the education of the firemen. At first there is a tendency to use too much coal, owing to the ease of firing.

Practically any kind of coal can be used on stoker engines, and almost every kind available is used among the 5126 engines now in service. Fine coal of poor quality, bituminous coal and anthracite are all employed, and even lignite has been handled successfully without increased throwing of sparks. It is the almost unanimous opinion of users of mechanical stokers that a crusher should be fitted on the tender, so that engine can work on different divisions where different grades of coal are supplied. But as the number of these engines increases it will become practicable to prepare the coal in advance, either at coaling stations or at some central point on the railway.

With the firing of the engines regulated by brain and thought instead of by muscular strength it is expected by most railways that a higher class of labour will be available for firemen, thus securing more efficient handling and providing a larger supply of men capable of becoming enginemen. At the same time, it must not be thought that the fireman has nothing to do on a stoker-fired engine. In order to secure efficiency and economy it is necessary for him to watch his fire and adjust it to varying conditions of speed, load, weather, and gradients. This is especially the case since the best results are obtained with a thin fire, and maintenance of such a fire needs constant attention. But it is attention of thought and skill instead of mere muscle. In fact, on one railway the blast pipes on the stoker engines have been so altered that the engines will not steam properly when the fire is more than about 6 in. thick.—The Engineer.

St. Thomas Gets Thrills.—The citizens at St. Thomas were evidently out for thrills during the recent convention of fire chiefs in that city. Two barrels partly filled with water, with six gallons of gasoline on top was the first thrill, a floor 12 by 14 feet, saturated with gasoline and kerosene was the second test, while the third thrill consisted of four boxes each 4 feet high and 3 feet wide, with a strip of gasoline three feet wide and 10 feet long leading to the boxes.

Last, but not least, as the circus barker would put it, came the spectacular feat. A structure of a frame of boards, 10 inches wide and 14 feet long, was erected in the shape of a triangle, the structure being open at all ends and the loose boards permitting draft from all sides. The floor was covered with excelsior and hay and a wagon load of hickory sticks, and an additional load of old lumber and boards was placed inside.

A barrel of gasoline was poured on the centre of this varied mass and the entire structure was saturated with the same material. A strip of gasoline, 15 feet, was led directly to the gasoline barrel which had been placed in the centre of the structure. All the above were duly ignited.

These tests were for a purpose, however, and not merely for display. The fire department used sand, soda and acid to extinguish the fires, but in all cases did not put them out. It was after such devices had tried to put an end to the blazes that the Canadian Foamite Firefoam, Ltd., who were conducting the tests, used their foamite firefoam with splendid success. In the last test a 40 gallon engine was used, this generating 320 gallons of foamite. In less than three minutes the fire was completely extinguished. The tests were conducted both for the benefit of the fire chiefs and manufacturers in general.

THE INTERCRYSTALLINE BRITTLENESS OF LEAD

According to an abstract in the "Journal of the Franklin Institute" of a U.S.A. Standard Bureau Note, sheet lead sometimes assumes a very brittle granular form during service, due to corrosion. An explanation which has been offered by previous investigators for this change in properties is that it is due to an allotropic transformation, the product resulting from the change being analogous to the well-known "grey tin." Contact with an electrolyte, particularly a weak acid solution of a lead salt, has been claimed to be the agency by which the transformation is brought about. Metallographic examination of the granular "allotropic" lead shows that each grain has the characteristic properties of the ordinary form of lead. The intercrystalline cohesion of the grains for one another, however, has been so weakened that the material has a granular appearance. The rate at which the intercrystalline brittleness is brought about is proportional to the amount of impurities and to the concentration of acid in the solution in which the lead is placed. Practically all the impurities which are found in lead are lodged in between the grain. The preferential attack by the corroding agent for these impurities and perhaps also for the "amorphous intercrystalline cement," accounts for the brittleness produced.

The Morse Chain Co., of Ithaca, N.Y., will have in their exhibit at the Sixth National Exposition of Chemical Industries a number of samples of different chains, showing the Morse Rocker Joint, from ½ in. pitch to 3 in. pitch, and in several widths illustrating the chain as used for ½ h.p. to 5,000 h.p.

The Rocker Joint will be shown in cross section and its fundamental, almost frictionless features, the guide links, and minimum oil requirements explained with reasons for the long life and success that has always followed the use of Morse drives for increasing production, and for difficult drives, where either dust, steam, gases, or moisture, ruin gears or leather belts and their slipping, taking up, and renewals, produce excessive costs.

Photographs of actual installations and results will be shown to those that are interested. Mr. T. G. Anderson, manager of the New York Office, will be in charge assisted by Mr. H. W. Evans, Sales Engineer. During the week, Mr. A. B. Wray, Chief Sales Engineer, and Mr. V. D. Morse, Manager of Sales, from the Ithaca office, will be present; while Mr. J. S. White, manager New England district; Mr. E. R. Morse, manager Baltimore office and Mr. M. H. Rodda, manager Philadelphia office will be there to greet their friends.

Their booth will be No. 611.

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

N THE joint considered in the last article the plate strength was 68.75, while the rivet strength was only 41.72 A single riveted lap joint should be about 50 per cent. strength, so that there is evidently some factor that requires altering. As the plate strength is higher than the rivet strength, it is observed that the factor that is wrong is the pitch. This is arrived at by considering that the plate is of minimum thickness, and the rivet cannot be decreased in diameter. As the pitch is a divisor in the formula for finding rivet strength, it is plain that by decreasing this factor the rivet strength percentage will be brought up. How much must we alter it to get the required figure? We can find that out very easily.

The formula for rivet strength we have seen is:

$$\frac{a \times n}{p \times t} \times C \times 100 = \%\text{ of rivet strength}$$

Now, let us insert the quantities we know. We have 50 per cent. for rivet strength, the other factors, excepting p remaining the same, and it is p we want to find. So we have

$$\frac{5\times5\times.7854\times1\times.85\times100\times16}{8\times8\times p\times5}=50$$

Then, P is the unknown quantity. We will work this out. First by cancellation we simplify the expression and get

$$\frac{5\times5\times.7854\times.85}{p}=50$$

Transferring we get

$$50p=5\times5\times.7854\times.85\times5$$

$$p=\frac{5\times5\times.7854\times.85\times5}{50}$$

$$p=1.66$$

The nearest fraction to this is 1⅝. Let us see how this works out on the plate strength. We have

$$\frac{p-d}{p}\times100=\%\text{ of plate strength}$$

Substituting figures we get

$$\frac{1\frac{5}{8}-\frac{5}{8}}{1\frac{5}{8}}\times100=\%$$

This is simpler expressed in decimals, thus

$$\frac{1.625-.625}{1.625}\times100=61.53\%$$

This is about right ,and we have a better balanced joint, with 61.5% plate and 50% rivet strength.

Analysis of Riveted Joints

In considering riveted joints, the various ways in which they may fail must be considered. The joint we are dealing with, being the most simple kind, has the least possible ways of failing. It can fail through the shearing of the rivets, and as there is only one rivet in the pitch limit the resistance of the joint to failing in that way will be the shearing strength of one rivet. It may fail by the plate tearing between the rivet holes, or it may fail by the plate crushing in front of the rivets.

The resistance offered by the plate to tearing between the rivet holes will be

$$p-d\times t\times60{,}000$$

or $(1.625-.625)\times.3125\times60{,}000$

$$1\times.3125\times60{,}000=18{,}750$$

and the percentage to the solid section will be:

$$\frac{18{,}750\times100}{30468.75}=61.53\%$$

This is in exact agreement with the previous result.

We must now consider the plate crushing in front of the rivet holes. We will have a section of plate equal to the diameter of one rivet and the thickness of the plate. The crushing strength of good boiler plate is about 90,000 lbs., so that we have

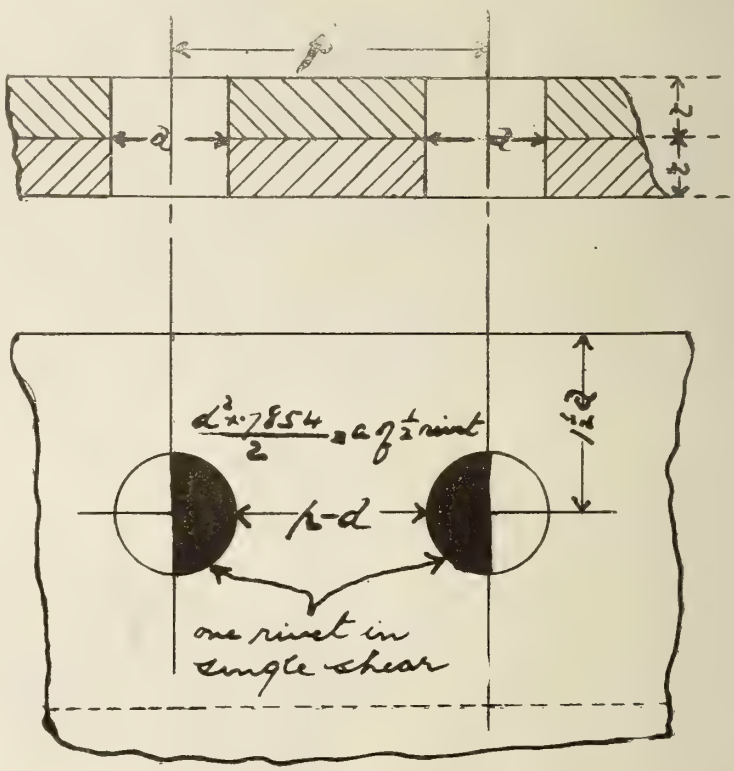
$$⅝\times5\text{-}16\times90{,}000=17571$$

This gives

$$\frac{17571\times100}{30468.75}=54.3\%$$

which is higher than the rivet stength percentage and may therefore be neglected.

We may say that a joint of this kind is practically never used in the longitudinal seams of a steam boiler, as its low percentage of strength would penalize every other part of the structure. However, they are sometimes met with



SINGLE RIVETED LAP JOINT

First of all consider the strength of the solid plate. We have a pitch of 1.625 inches, with a thickness of 5-16 of an inch, and a tensile strength of 60,000 lbs. per square inch. The strength of the section will then be

$$p\times t\times60{,}000$$

$$=1.625\times.3125\times60{,}000$$

$$=30468.75\text{ lbs.}$$

Then the strength of one rivet in single steel will be if tensile strength of rivet stub is 51,000 (.85 of plate strength) $⅝\times⅝\times.7854\times51{,}000$.

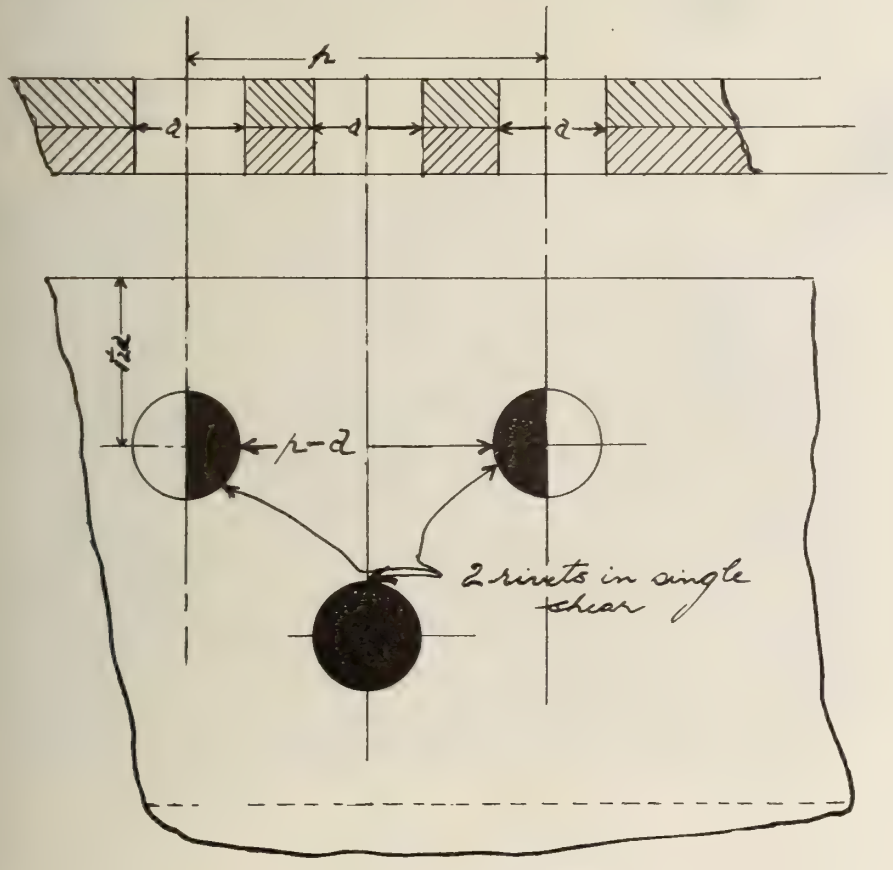
This worked out is 15,300 and the percentage to the solid plate is

$$\frac{15{,}300\times100}{30{,}468.75}=50.2\%$$

on steam domes, where the small diameter in comparison to weight of plate elbows allows a low percentage joint to be used. In tank work, where the thickness of plate is much more than is necessary to resist the pressure, a single riveted lap ojint is often used. For purely steam boiler work it is hardly to be considered. The next type of joint, and one very widely used, is the double riveted lap joint.

The Double Riveted Lap Joint

This joint has two rows of rivets, and two rivets in a pitch. It is usually designed for a strength of about 70 per cent. of the solid plate rivet strength and plate strength being approximately



DOUBLE RIVETED LAP JOINT.

equal. The same formulae are used in making the calculations, but a new factor is a formula for determining the distance between the rows of rivets. The Ontario regulations prohibit chain riveting, all rows of rivets having to be staggered, or zig-zag.

Let us take a concrete example and work it out, which is the best way of explaining it. Let us assume we want a boiler built of ⅜ inch plate and having a double riveted lap joint of about 2 per cent. strength. We want to get the other dimensions. The diameter of rivet may be taken as ¾ inch, or double the thickness of the plate. Very often in practice the rivet hole will be 13-16 in this size of plate, and of course the rivet size after driving will be the same as the diameter of the hole. Using the larger diameter in the calculations makes a slightly higher percentage of rivet strength and a slightly lower plate strength. However for our purpose we will consider the diameter as ¾. Now we want to find the pitch that will give the requisite strength with this diameter of rivet. We come back to the formula.

$$\frac{p-d}{p}\times 100 = \%\text{ of plate strength}$$

Substituting we get

$$\frac{p-d}{p} = .72$$

$$p-d = .72\ p$$

$$d = .28\ p$$

Then if d=.75 we get

$$.28\ p : p :: .75 : x$$

which gives

$$\frac{.75\ p}{.28\ p} = 2.679 \text{ inches}$$

as the pitch we require. Knowing the diameter of rivet and thickness of plate, and number of rivets in a pitch, we could have found the pitch from the formula for rivet strength, as we did in the case of the single riveted joint. We will in this case, see how the pitch we have found works out for rivet strength. We have

$$\frac{a\times n}{p\times t}\times C\times 100 = \%\text{ rivet strength}$$

Substituting figures we have, using .70 as the constant C in this case, and 2 11-16 as the pitch

$$\frac{3\times 3\times .7854\times 2\times 70\times 16\times 8\times 100}{4\times 4\times 43\times 3\times 100} = \%$$

This worked out gives a percentage of 61.37, which is too low. We wish to make our joint about even, though if the plate strength is a little higher than the rivet strength it is all to the good, as the plate strength may deteriorate in time, through the corrosion or thinning of the plate, which will not likely occur with the rivet.

We can use still another method if we wish, and that is to equate the two strengths to each other, and thus arrive at a pitch that will satisfy both.

This means that if the strength is to be equal, the two formulas must be equal to each other. Let us state this in the form of an equation. We have

$$\frac{p-d}{p}\times 100 = \% \text{ and } \frac{a\times n\times C}{p\times t}\times 100 = \%$$

If these % are equal the other sides must be equal, so we have

$$\frac{p-d}{p} = \frac{a\times n\times C}{p\times t}$$

$$p-d = \frac{a\times n\times C\times p}{p\times t}$$

$$p = \frac{a\times n\times C}{t} + d$$

Here we have arrived at an expression for pitch which should satisfy us. Let us substitute figures and see

$$p = \frac{3\times 3\times .7584\times 2\times 8\times 70}{4\times 4\times 3\times 100} + ¾$$

$$p = 2.39, \text{ say } 2.4$$

so we get 2.4 as a pitch. Let us try this again for our plate and rivet strength. First for plate percentage:

$$\frac{2.4-75}{2.4}\times 100 = 68.75$$

Then for rivet strength

$$\frac{3\times 3\times .7854\times 2\times 5\times 8\times 70\times 100}{4\times 4\times 12\times 3\times 100} = 68.72$$

Here we have got a perfectly evenly balanced joint, and though it is some 4% lower than we at first determined on, that is not a very serious matter.

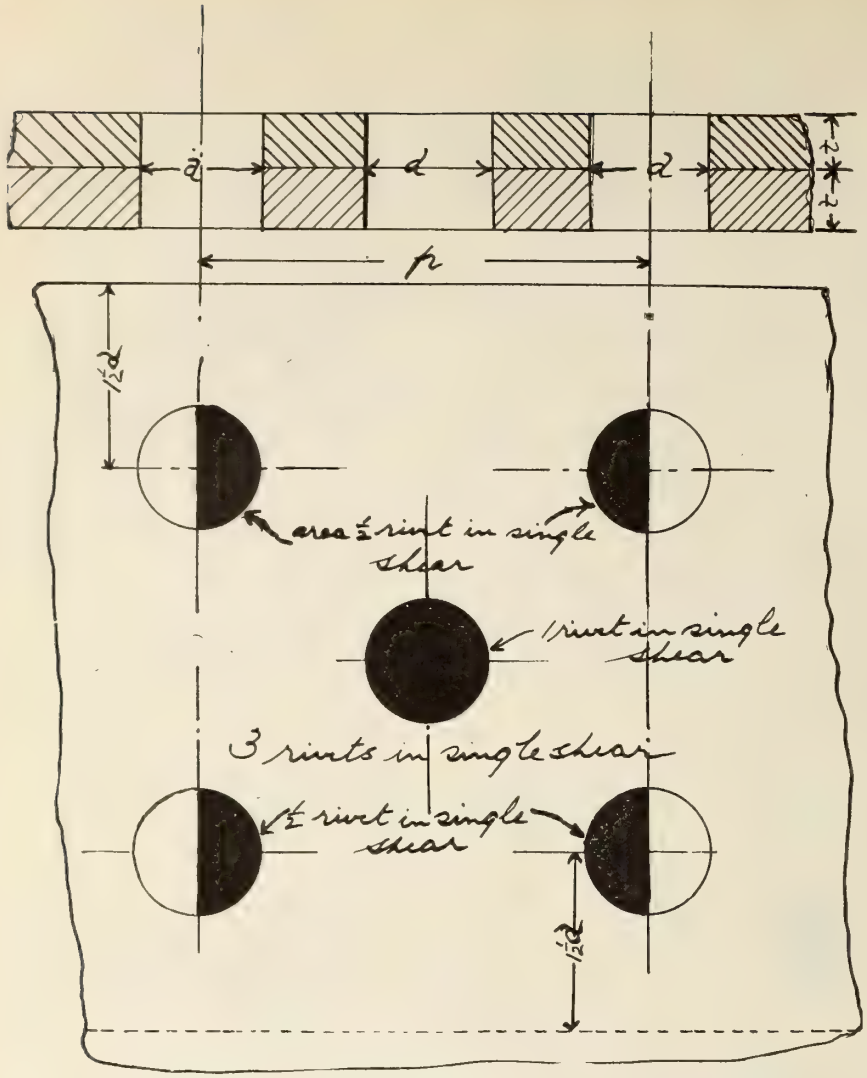
Let us see now how this joint stands comparison in its resistance to failure at different points. It may fail by rupturing between two rivet holes in the outer row and shearing one rivet. It may fail by shearing two rivets, or by tearing between the rivets on the inner row. It can also fail by crushing in front of the rivets in the outer row, and shearing the inner rivet, or by shearing the rivets in the outer row and crushing in front of the rivets in the second row. Let us take these in order. First the unit section is $p\times t\times 60{,}000$

$$2.4\times .375\times 60000 = 54{,}000$$

If the plate tears between two rivets on the outer row, and shears the rivet in the inner row it will have to overcome a resistance of

$$60000\ (p-d)\ t + a\times .7\times 60000$$

That is, the plate has diameter of one



TREBLE RIVETED LAP JOINT

rivet, plus the area of one rivet in single shear, whose resistance to shearing is .7 that of the plate tensile strength. Substituting figures we have

$$2.4—.75)\times.375\times60000+75^2\times.7854\times42000$$

which gives 74,250 or more than the solid plate. If it fails by shearing two rivets we have

$$a\times2\times42000$$
$$=.75\times.75\times.7854\times2\times42000$$
$$=37102 \text{ lbs.}$$

$$\text{which is } \frac{37102}{54000}\times100=68.7\%$$

of the solid

If it tears between two rivets on the inner row, we shall have again

$$\frac{(p—d)\times t\times60000}{(2.4—.75)\times.375\times60000}=68.7\%$$
$$54000$$

If it crushes the plate in front of the rivets in the outer row and shears one rivet in the inner row we have then

$$(d\times t\times90000)+(a\times42000)$$
$$(.75\times.375\times90000)+(.75^2\times.7584\times42000)=43872.3$$

$$\text{and } \frac{438723}{54000}\times100=81.2\%$$

which is much higher than either the plate or rivet %. The last two cases are exactly the same as each other so we see that 68.7% is the strength of the joint. The minimum distance between rows of rivets is found from the formula.

$$\frac{(11\frac{1}{2}+4\ d)\ (p+4\ d)}{10}=\text{minimum distance}$$

The treble riveted lap joint shown in the sketch is not very much used, as there is not much advantage in employing it. The percentage obtainable is not much greater than with the double riveted joint, and the cost of manufacture is increased. The calculations are made exactly in the same way as for a double riveted joint, excepting that there are three rivets in single shear instead of two. It may fail by the plate breaking between the outer rivets and shearing two rivets. It may crush the plate in front of one rivet and shear two rivets. It may shear three rivets. The plate may break between the rivets in the centre row and shear one rivet in the inner row. It may fail between the rivets in the inner row, and this of course is the weakest part, so that

$\frac{p—d}{p}$ is the governing factor.

The calculations would be as follows:

1st case — (p—d) t×60000+a×2×42000.

2nd case—d×t×90000+a×2×42000.

3rd case—a×3×42000.

4th case—(p×d) t×60000+a×42000.

42000.

5th case—(p—d) t×60000.

In the next article we will take up butt joints.

NEW USES FOR COMPRESSED AIR

It is not generally known that compressed air is used in various ways in the tobacco industry, yet such is the case, and the following description, which appeared in "Compressed Air Magazine" should be of special interest. The author is chief engineer of the R. J. Reynolds Tobacco Co., Winston-Salem, N.C., and he comments as follows:

"The regular tools such as the rock drills for concrete work, and the machine shop equipment for drilling and driving rivets, chippings, etc., and also a few hoists using compressed air are in use but do not require any further mention as they are of standard design. Compressed air is used for blowing motors and machinery in general, to remove the dust, and in places in automatic machines where the fine tobacco droppings have a tendency to gum and clog the machine in a few hours; a fine jet of air was placed to remove this dust, the trouble was removed, and the machine could run along its full time.

"The same principle is used in another process where it assists in drying and also blows away any dust, while a quick-drying paste is setting. This has very extensive application in plants and has made the installation of several large compressors necessary.

"In making the 'Prince Albert' can tops they are blown clear off the die by air pressure, and just to show that it's an ill wind that won't work both ways, sheets of tin used in making the cans are picked up by means of un-compressed air, or a vacuum.

"A battery of boilers is so placed that they are below any drainage or storm sewer line. When these boilers are blown down a few inches under pressure, no complications result, but when they are cooled down naturally, as they should be, and so have no steam pressure on them to blow out their water up to the sewer, a compressed air connection empties them very successfully.

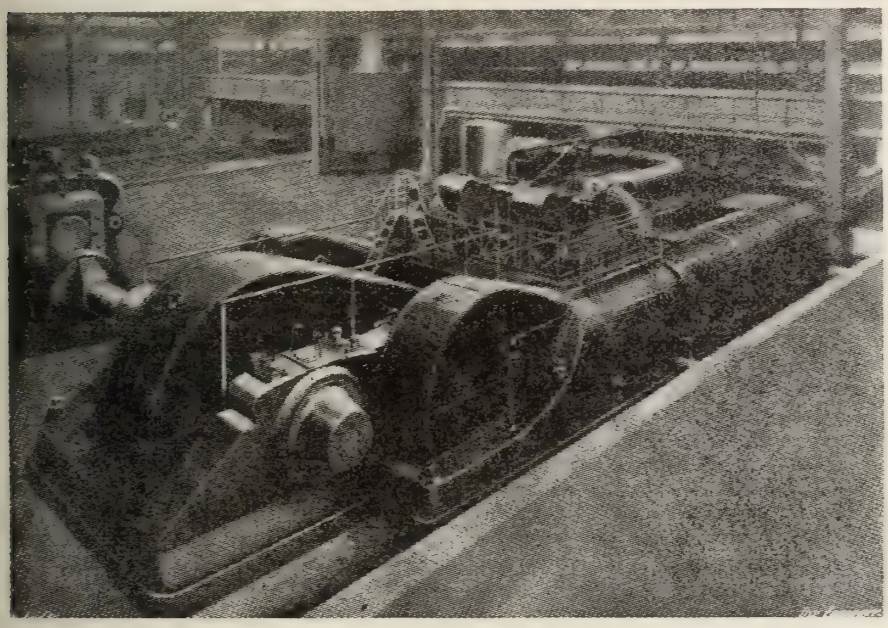
"The air is of great use and assistance in spraying liquids for conditioning dry tobaccos. The sprayer acts on the principle of the ejector and will pick up the liquid by suction for several feet rise.

"With a pressure-reducing valve in series, there is much use made of the compressed air, for the purpose of low pressure control of heating valves, humidity apparatus and similar equipment."

A 25,000 HORSE-POWER MILL ENGINE*

To meet the demand for plates from which the ends of large marine boilers can be cut in one piece, the Lukens Steel Company, of Coatesville, Pa., U. S.A., has recently installed a rolling mill measuring 17ft. between the housings and capable of rolling plates up to 16 ft. wide. The chilled iron working rolls are 34 in. in diameter, and are backed up by cast steel rolls 50 in. in diameter.

When the question of driving this mill arose, it was decided to adopt a steam engine in preference to electric motors, as, although the latter are generally accredited with the greater starting torque, installation of two 12,000 horsepower reversing motors and extensions to the power plant which would be required was considered too great an undertaking. An order was thus given to the Mesta Machine Company, of Pittsburg, for a 25,000 horse-power steam engine, a photograph of which we reproduce.



25,000 H.P. ENGINE.

The engine is of the horizontol twin-tandem geared type, having high-pressure steam cylinders, 46 inches diameter, low pressure steam cylinders, 70 in. dia., and a stroke of 60 in. The mill is driven from the jack shaft of the engine, which is connected with the main crank shaft by cast steel double helical cut gears, in the ratio of 2:1. The main shaft of the engine run normally at 150 revolutions per minute and the jack shaft 75 rev. per minute, the normal speed of the mill. The teeth in the reduction gears are 54 in. across the face and 7.625 in. circular pitch. The high pressure cylinders are designed for a steam pressure of 225 lb. per square inch and the low pressure cylinders for 100 lb. per square inch. The bed-plates are of the Tangye type. with bored guides, cast in one piece and are supported their entire length on the foundation. The weight of each of the bed-plates is 200,000 lb. The total weight of the engine is 1,400,000 lb. (about 625 tons.)

The link motion connecting up with the piston valves on the cylinders is of the Stephenson type. The link is carried directly on the valve stem guides for the high-pressure cylinders, thus minimizing lost motion and giving a direct drive from the eccentrics to the valves. The reversing mechanism consists of a steam-operated cylinder, directly connected by the same piston-rod to an oil check cylinder, the crosshead between being connected to the tumbling shaft. The reversing mechanism is also connected with and operates the throttle valve. The engine is controlled by a single lever in the operator's pulpit, and the links can be held without effort in any position. When the links are brought to their central position for either forward or backward running of the engine, the throttle valve automatically opens very rapidly so that the engine is always running on cut-off without any throttling of the steam. In the older types of reversing engines where two operating levers were employed, one for handling the reversing gear and the other for handling the throttle, it depends entirely upon the operator whether the engine is run economically by utilizing the expansions of the steam, or uneconomically by having the links always set in their extreme position and running on the throttle alone. The steam saved in operating a large engine of this kind by means of the single lever control arrangement ,may be, the makers say, as much as from 20 to 30 per cent. They also claim that the engine accelerates in less time than would ever be possible with a motor, on account of the comparatively light rotating masses, and reverses in about half the time that would be required for an electric motor operating the same mill. —*Engineering.

RARE METALS IN ONTARIO

In addition to being the premier mining province of Canada as regards gold and silver, Ontario produces other rare metals that are even more valuable than gold. During the past year platinum and palladium were recovered at Port Colborne, and also by the International Nickel Company at its Bayonne refinery. At the latter, 19,628 tons of Bessemer matts were treated during the year, from which platinum, palladium, rhodium, osmium, iridium and ruthenium were recovered. In all 1,770 fine ounces were obtained, the estimated value being $200,000. Quotations on the rarer metals are difficult to obtain, the average price of platinum for the year being $114 per fine ounce. Palladium has been valued at $1.30. Iridium is now quoted nominally at $500 per ounce troy. The average value of iridium imported into the United States in 1916 was $114, and for osmium it was $58 per ounce in 1917.

The Rich Tool Company, Chicago, announce that the Garlock-Walker Machinery Co., Ltd., with offices in Toronto, Montreal and Winnipeg, have been appointed their exclusive agents for Canada.

Report on Peat Possibilities.—The Hon. Harry Mills, Minister of Mines in the Ontario Government, has received an interim report from the officials investigating the Alfred peat bog. The report asks for a further extension of a year before a report in full is given. Mr. Mills, however, thinks that enough time has been spent to secure all information, and wants the complete report in this year.

Big Industry For Quebec.—A large amalgamation of British firms is contemplating the establishment of a large matchmaking factory in Quebec, according to a statement by Sir Alfred Maguire, who has been in Canada for some weeks investigating. There will be a 50 per cent. Canadian board, and the names of Sir Lomer Gouin and George Cahoon are mentioned as members of the board, which will consist of twelve.

PERSONAL

At a special meeting of the Chatham city council it was decided to engage C. H. R. Fuller, of Toronto, as city engineer at a salary of $3,000 a year. Mr. Fuller is a Bachelor of Applied Science at Toronto University and is at present being employed by the Imperial Oil Co. He served in France with the same company of railway troops as Major Frank P. Adams, the retiring city engineer, who assumes a similar post in Brantford.

Principles of Alternating Current Motors

The Fundamental Characteristics and Operating Features of the Synchronous Motor Are Discussed by the Author.

TERRELL CROFT

ALL alternating-current motors may be classified into two general divisions as shown below. Furthermore, asynchronous motors may be further sub-divided as indicated, thus:

- (1) Synchronous Motors
  - Single-Phase
  - Polyphase.
- (2) Asynchronous Motors—
  - (a) Induction Motors
    - Single-Phase
    - Polyphase.
  - (b) Commutator Motors (Single-Phase)
    - Series
    - Compound
    - Shunt
    - Repulsion

The fundamental operation principle is the same for all electric motors, both alternating current and direct current. That is, in every case, rotation of the rotor is due to the magnetic interaction between a current-carrying conductor and a magnetic field in the motor in which the conductor finds itself. In compliance with well-established laws there is always a magnetic force tending to thrust such a conductor from the field. It is this tendency which produces rotation of the rotor. Furthermore, in every motor (both a.c. and d.c.) the current, which is forced through the armature is limited by a counter or back e.m.f. value which is deevloped in some fashion or other in the motor. The e.m.f., which is actually effective in forcing current through the motor is, then, not the line voltage but it is the difference between the line voltage and this counter voltage which is produced in and by the motor. The value of the counter e.m.f. is always such that it tends to limit automatically the current compelling the motor to that value which is necessary to "pull" the load then on the motor. Thus, when the load on any electric motor is heavy, the counter e.m.f. then developed by the motor is relatively small. And a large current, whereby the load may be pulled, is permitted to flow. When the load is light the counter e.m.f. becomes small automatically. Thus current through the motor at light load is limited to a low intensity.

How the Synchronous Motor Works

Operation of the synchronous motor is due to the same general phenomena as that to which the operation of every other kind of electric motor is due. First an impressed or line e.m.f. (it must be an alternating e.m.f. for a synchronous motor) must be provided which will impel current through the armature of the machine. Then its rotor is caused to turn by virtue of the magnetic interaction between the current-carrying conductors on the armature and the magnetic field. A counter e.m.f. is produced by the armature conductors cutting through the field as the armature rotates. This limits the current through the armature. As the load on the motor becomes greater the counter e.m.f. decreases, permitting more current to flow to produce more power. If the load on the motor decreases the counter e.m.f. is correspondingly increased, decreasing proportionately the power taken by the motor. Always, however, the power in watts taken by the motor equals the product of the input current and the active or energy e.m.f. (not the line e.m.f. necessarily). An explanation of just how these phenomena produce rotation of a synchronous motor will be given in succeeding sects.

The construction of the synchronous motor is practically identical with that of the alternating-current generator. In fact, any commercial alternating current generator will operate as a synchronous motor. Hence it follows that synchronous motors may be of either the revolving-armature or the revolving field type. Furthermore, they may be single-phase or polyphase. However, practically all modern machines are revolving armature and three-phase. Figs. 1 and 2 show typical medium-capacity and large-capacity machines. The revolving field windings are excited with direct current impelled by an exciter. The single-phase synchronous motor is not self-starting but must, by some external means, be brought up to synchronous speed before it will carry its load. The polyphase motors can be made self starting where they can start without much load. Where a polyphase motor is to be self-starting, its rotor must be provided with a squirrel cage winding (Fig. 3). The constructions and characteristics just outlined will be treated in detail in sects. which follow.

The speed of a synchronous motor is always synchronous speed. Its speed regulation is 100 per cent. That is, the operating speed of such a motor is, for reasons which will be explained, determined wholly by the frequency of the supply circuit and the number of poles on the machine. There are certain rules and formulas whereby the synchronous speeds of alternating current generators and induction motors are computed. The same rules and formulas are used for finding the speeds of synchronous motors. If a load greater than its capacity is imposed on a synchronous motor, it will then not operate at a speed lower than the synchronous, but will merely "drop out of step" and stop. Why the same formulas are used for computing the speeds of alternating current generators and synchronous motors is explained in a succeeding sect.

Note.—A synchronous motor operates at the speed at which it would if it were driven as a generator have to operate to develop the frequency of its supply circuit. Thus a synchronous motor turing at synchronous speed is said to be operating in "synchronism" or in step with the generator which serves it.

The general characteristics of the

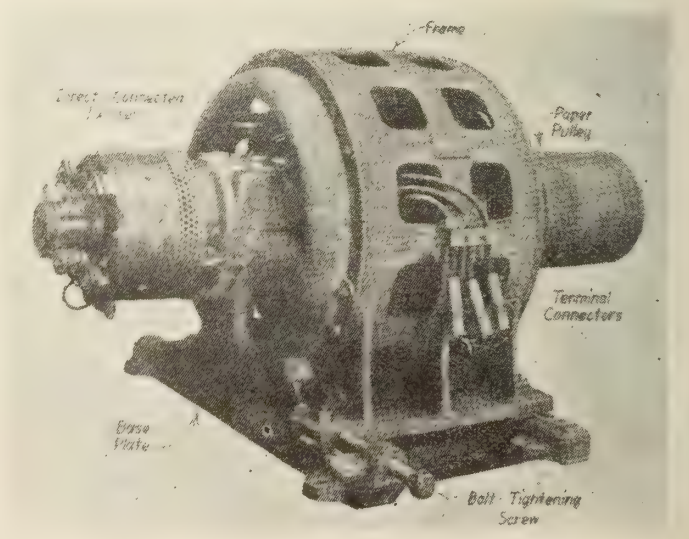


FIG. 1—Typical revolving-field, two-bearing, belted, synchronous motor. (This is a 187-h.p., 100 per cent. p.f., 900 r.p.m., 2300-volt, 3-phase, 60-cycle Allis-Chalmers machine. The exciter is direct connected.)

FIG.2—Typical three-bearing, belted, revolving-field, large-capacity synchronous motor. (A 200-h.p., 600-r.p.m., 2300-volt, 3-phase, 60-cycle machine of the Electrical Machinery Company, Minneapolis, Minn.)

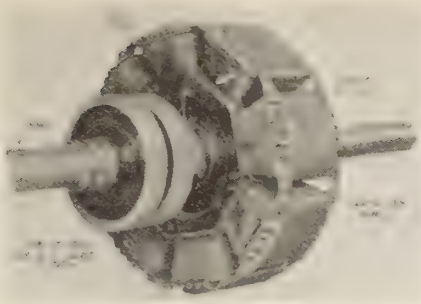

FIG. 3—Eight-pole, rotating field of a self-starting synchronous motor showing "squirrel-cage" starting winding in slots in pole faces. (Electrical Machinery Co., Minneapolis, Minn.)

synchronous motor (the why in each case will be explained below) are these:

(1) It is, as described above, primarily a constant speed motor.

(2) If the synchronous motor is overloaded its breakdown point or maximum output value is reached; its speed decreases and it stops.

(3) By varying the excitation of the direct-current field the motor can at will be made to take a leading or lagging current from the line. When under-excited, the current through it will be lagging. When over-excited, the current will be leading. When the current through an over-excited synchronous motor is leading, its effect on the circuit is then similar to that of a permittor or condensor in the circuit. Hence the machines when thus used are called synchronous condensers. By virtue of this characteristic synchronous motors or condensers can be utilized for the raising of the power factor of a circuit.

(4) The starting torque is small. The single-phase motor has no starting torque is small. The single-phase motor torque and the polyphase motors have a very low starting torque (about 25 per cent. full load torque) which is seldom sufficient to start a mechanical load of any consequence.

Advantages and disadvantages of the synchronous motor may be recited thus:

Advantages, which may, however, in certain cases be disadvantages:

(1) Constant-speed operation at all loads within its range, assuming the supply circuit to be of constant frequency.

(2) Power factor of the power which it takes is under control of the attendant.

(3) Can be used for raising the power factor of the circuit on which it operates. It can be used solely either for correcting power factor or for driving a mechanical load. Or it may be used for the simultaneous correcting of low power factor and the driving of a mechanical load.

Disadvantages

(1) Low starting torque.

(2) No possibility of speed control.

(3) Source of direct current required for field excitation.

Fundamental operating principles of the synchronous motor can be understood from a consideration of the arrangement of Fig. 4.

Explanation

A is a long, heavy stationary iron bar on which are mounted downwardly-projecting pole pieces, N. S., etc. These poles are excited by alternative current impelled by the alternator G. Although only five poles are shown, this bar with equidistantly-spaced poles on it is assumed to extend for an indefinite distance in each direction. The alternating current winding is reversed on alternate poles of A. Hence with the alternating current due to G considered at some given instant and in a certain direction (for example, in the direction shown in Fig. 4) the poles will be at that instant of different polarities, N, S, N, S, etc., along the bar indicated. But with each alternation of the alternating current the polarity of each pole will reverse.

F is a truck mounted on wheels and travelling on rails, R. Thus F may be moved along under the poles of A longitudinally either to the right or to the left. On the iron body of F are mounted four upwardly-projecting poles. The winding of these is energized with direct current from the exciting generator E, which is supposed to move with the truck. The winding is reversed on every other pole of F. Hence the polarities of these direct-current poles will be S, N, S, N, as shown. Since these poles are excited with direct current, their polarities will be always those indicated.

At the instant pictured in the illustration with the current from G in the direction shown, the unlike polarity poles on A and on F attract one another. There is, then, a force tending to move F toward the right at the instant shown. But if F is not thus shifted toward the right, then, when the current from G reverses in direction, the polarities of the poles on A will be such that there will be a force tending to shift F toward the left.

However, assume that F is moved toward the right by the attractive force of the unlike poles of F and A. Then if the alternating current which excites A reverses before P_2 attains a position under P_1, F will be forced back toward the left because the polarities of all of the poles of A will be reversed simultaneously. Again if P_2 shifts to the right and past P_1 before P_1 reverses then P_2 will be pulled back. But if P_2 reaches a position just under P_1 as the polarity of P_1 is changed by the reversal of the alternating current, then F will be forced ahead to the right.

Thus if F is started by some outside force toward the right at such a speed that it travels the distance D (Fig. 4) between any two adjacent poles on F in the time occupied for one alternation of the alternating current due to G, F will continue to move. If it is started toward the left at this speed it will continue to move toward the left. If it is started toward the right at this speed it will continue to move toward the right. If F is not started at the correct synchronous speed it will not continue to move longitudinally but will merely oscillate through the distance D.

The arrangement of Fig. 4 illustrates the principle of the synchronous motor. In actual synchronous motors the alternating current poles are inside of a stationary ring and the direct current poles are mounted on a rotor which rotates within the ring (see Fig. 8).

Why the synchronous motor can operate only a synchronous speed will be evident from a consideration of Figs. 5, 6, and 7. In these illustrations the truck F, of Fig. 4 has been replaced by a bar F_1, F_2, etc., which is supposed to extend indefinitely in each direction. Mounted under the bar at intervals are wheels upon which it can roll. The poles S, N, S, N, etc., carried on F are supposed to be excited by direct current to the polarities indicated. To simplify the illustration the exciting winding is not shown. In Figs. 5 and 6 it is assumed that the bar F is moving toward the right at synchronous speed. These two illustrations trace the movement during

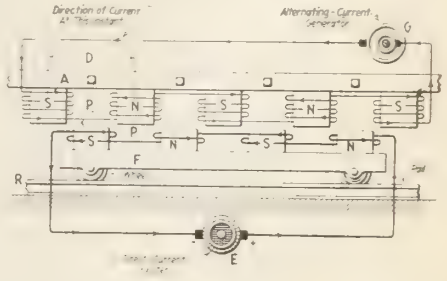

FIG. 4—ILLUSTRATING THE PRINCIPLE OF THE SYNCHRONOUS MOTOR.

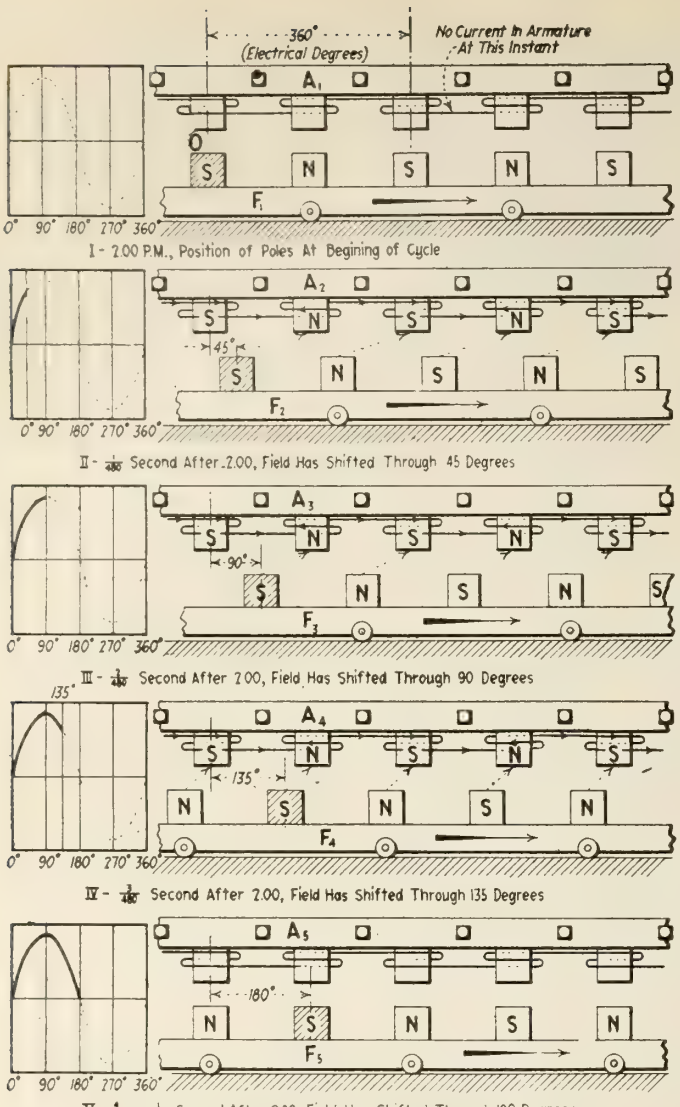
one complete cycle. It is assumed that the frequency of the exciting current is 60 cycles, and that our examinaiton of the situation starts at exactly 2 o'clock p.m.

Concentrate attention on the pole S, which is cross-sectioned to identify it. 1/480 sec. after 2 p.m. the alternating current wave has passed through 45 deg. and the field F_2 has, by the magnetic interaction, been shifted to the right through 45 electrical degrees. Likewise, tracing the operation through the pictures III to VII it will be noted that the 60-cycle alternating current completes one cycle during 1-60 sec. and during that time the pole S is impelled through a distance equal to that between centres of unlike poles. That is, it is shifted (VII) through 360 electrical degrees. Conditions remaining the same, the field F would continue to shift to-



360° (Electrical Degrees)
No Current In Armature At This Instant
I - 2.00 P.M., Position of Poles At Begining of Cycle
II - 1/480 Second After 2.00, Field Has Shifted Through 45 Degrees
III - 1/240 Second After 2.00, Field Has Shifted Through 90 Degrees
IV - 1/160 Second After 2.00, Field Has Shifted Through 135 Degrees
V - 1/80 or 1/120 Second After 2.00, Field Has Shifted Through 180 Degrees

FIG. 5—Showing how the Moving Field of a Synchronous Motor must shift along at "Synchronous" speed. (On a 60-cycle circuit, conditions for which are pictured above, the direct-current-excited field, **F**, will, if it moves at synchronous speed—and it must move at synchronous speed if its operation is to continue—shift exactly the distance **OP** between centers of adjacent like poles in 1/60 second. This distance, **OP**, always equals 360 electrical degrees. But the actual spacing **OP** between like poles in inches or in feet in an actual motor depends on the size and speed of the machine.)

ward the right at the same speed as long as its excitation with direct current and the excitation of the armature A with alternating current continued.

A study of the illustrations of Figs. 5 and 6 will render it evident that the shifting could not be otherwise than at synchronous speed. Thus each direct current pole on F must shift through the distance between alternate poles (360 electrical degrees) of the armature A, in the same time that a field pole of the alternating current generator, which is supplying power, passes between two successive poles on its armature.

If, as suggested in Fig. 7, the field F had been shifted to the right through only 90 deg. while the current wave had passed through 225 deg. (as shown in the graph at the left) then the magnetic interaction at this instant between the like polarities would be such that the field bar would be impelled to the left instead of toward the right. Its motion would be reversed, showing that F must move at synchrous speed if its uniform motion in one direction is to continue.

The relation of speed, frequency and number of poles in a synchronous motor can be understood by a study of Fig. 8. Assume that a portion of the armature A of Fig. 5 with two extending poles, p_1 and p_2, on it is bent into a ring and shown in Fig. 8, I. Also assume that two of the direct current poles, N_1 and S_1, are mounted diametrically opposite one another on a shaft. Then, if p_1 and p_2 are excited with alternating current and N_1 and S_1 are excited with direct current, the rotor R thus formed will revolve within the armature if it is first brought up to synchronous speed. It is evident from what has been described in connection with Figs. 4 and 5 that in this two-pole machine the rotor R will complete one revolution (that is, pass through 360 electrical degrees, the distance between like poles) during one cycle of the alternating current supply.

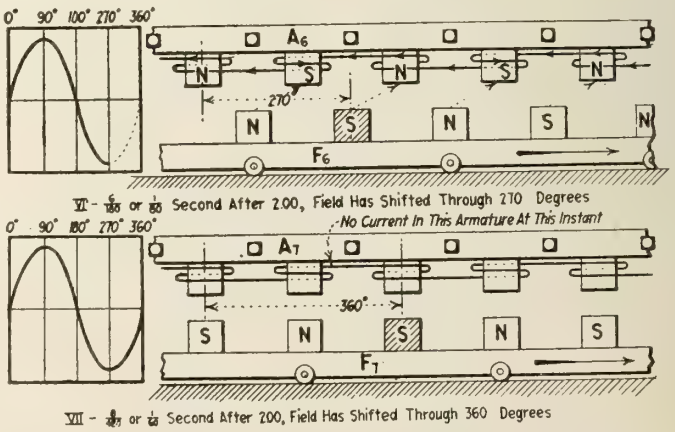
If the frequency is 1 cycle per second the rotor R will make 1 revolution per second. Now, if a four-pole motor be arranged as at II (Fig. 8) it is evident that, during 1 cycle, a field pole will pass through only half revolution. Therefore, with this 4-pole machine and a frequency of 1 cycle per sec. the motor would make two revolutions per second. Thus, in making one complete revolution the field of any synchronous motors turns through 360 mechanical degrees. The number of electrical degrees through which it turns depends upon the number of poles. Obviously: rev. per sec. = cycles + (number of poles + 2). Or simplified: Rev. per sec. = (2 × cycles) + number of poles. Then the rev. per min. will (since there are 60 sec. in a minute) equal 60 × (2 × cycles) number of poles = (120 × cycles) + number of poles. It will be noted by referring to Art. 713 in the author's "Pracitcal Electricity" that the equation just given is the same as that, there derived, for determining the speed of an alternating current generator.

Example.—What is the speed of an eight-pole, 60-cycle, synchronous motor (Fig. I, 276, 2A)?

Solution.—Substitute in above equation: r.p.m. = (120 × cycles) + poles = (120 × 60) + 8 = 900 r.p.m.

Example.—It is desired to instal on a 60-cycle circuit a synchronous motor which will operate at 1,200 r.p.m. How many poles will this machine have?

Solution.—Substitute in equation:



VI - 1/180 or 1/60 Second After 2.00, Field Has Shifted Through 270 Degrees
No Current In This Armature At This Instant
VII - 1/240 or 1/120 Second After 2.00, Field Has Shifted Through 360 Degrees

FIG. 6—A CONTINUATION OF FIG. 5, SHOWING OPERATION OF A SYNCHRONOUS MOTOR ON A 60-CYCLE CIRCUIT.

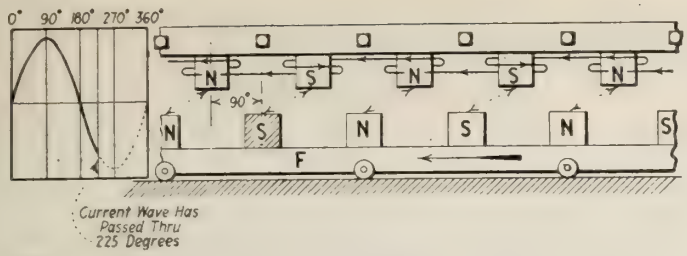


FIG. 7—Current wave has passed through 225 degrees, but slowly-moving field has passed through only 90 electrical degrees. Electro-magnetic repulsion tends to move the field toward the left.

number of poles (120 × cycles) + r.p.m. = (120 × 60) + 1200 = 6 poles.

Example.—It is known that a certain motor has 10 poles and that its operating speed is 300 r.p.m. What must be the frequency of the supply circuit upon which this machine is used?

Solution.—Substitute in the formula: Cycles = (poles × r.p.m.) + 120 = (10 × 300) + 120 = 25 cycles.

Note.—In the author's "American Electricians' Handbook" there is a table

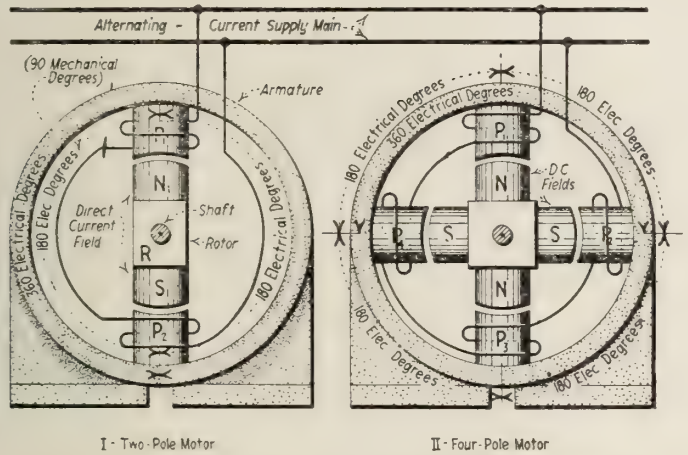

FIG. 8—ILLUSTRATING WHY THE SPEED OF A SYNCHRONOUS MOTOR IS DETERMINED BY THE NUMBER OF POLES.

of synchronous speeds of alternating current motors and generators for the commonly used frequencies between 25 and 133 cycles and for the commonly used numbers of poles between 2 and 100.

A HAIR-BREADTH ESCAPE

It has been very appropriately said that the number of boiler explosions that are prevented through the advice of inspectors can never be known. This fact, while fortunate for the community at large, detracts a great deal from the credit that properly belongs to the inspector if appearances are taken as the only criterion in judging the results of his labors. Every now and then however we meet with a situation where surely an explosion would have occurred involving heavy death toll and enormous property damage were it not for the inspector's timely advice based on his intimate familiarity with steam boilers and their appendages.

A short time ago the manager of a news-printing establishment in a Middle-Western city telephoned our local representative stating that the safety valve on their boiler was blowing continually but that they were unable to raise the pressure high enough to operate the engine. He further said that their engineer had attempted to adjust the safety valve until he had screwed it down to a point where the spring broke. The boiler had then been cooled down and a new safety valve set at the desired pressure was installed, but this gave no better results as regards pressure. The new valve continued to blow and still not enough pressure to run the engine.

As the printing of the first edition of the newspaper was being considerably delayed for lack of motive power, they desired to know whether it would not be all right to plug the safety-valve opening and station a man at the steam gauge to guard against over-pressure until the day's work was finished. Our representative, sensing the danger and instinctively, as it were, feeling what was wrong with the installation, requested that they immediately bank the fire and await the arrival of an inspector.

Upon looking over the installation the inspector found the steam gauge on the boiler registering 15 lbs. pressure and the engineer called his particular attention to the fact that the gauge in the engine room also showed 15 lbs. Two steam gauges registering the same. Was not that proof that the trouble must be elsewhere than with the gauges?

Our inspector found, however, that the two gauges were connected to a single pipe which led to the upper water column connection and that this connection was choked which prevented the steam gauges from indicating the actual boiler pressure. It is quite probable that the amount of over-pressure, at the time that the safety valve had been screwed down until the spring broke, was very great and in fact it may have been very close to the bursting pressure of the boiler. At any rate we feel that the persons that were near the boiler at the time the engineer was experimenting with the safety valve are to be congratulated with their escape from a violent death. As the boiler was located in the basement of a four storey building filled with people, the loss of life would undoubtedly have been very heavy.

It is really strange that any one, with even a slight knowledge of the make-up of a spring-safety-valve can imagine that such a valve will all of a sudden begin to relieve the boiler at a much lower pressure than that at which it is set, but somehow there appears to be a tendency in the human mind to regard the indications of the hand on the steam gauge dial as absolute. When a marked difference shows up between the pressure indicated by the steam gauge and the relieving pressure of the safety valve, the first inclination seems to have been, in a number of unfortunate cases, to go for the safety valve.

We cannot bear down with too much emphasis on the warning to **let the safety-valve adjustment alone** after it has once been set to relieve at the desired pressure, unless of course, a small change in the working pressure is expressly wanted under normal circumstances. One of the principal functions of the safety valve is to take care of just such conditions as the derangement of the steam gauge. Blind confidence in the steam gauge has been the direct cause of a number of boiler explosions on record and these explosions have been particularly violent. This, no doubt, is due to the fact that a very high pressure may be reached when the safety valve is overloaded and consequently an enormous amount of energy is stored up within the boiler.

One of these unfortunate cases was the explosion that took place on the U.S. gunboat "Bennington" on July 21st, 1905, while at anchor in the harbor of San Diego, Cal. In this instance a boiler was fired up from a cold condition. After the water in it had been brought to boiling temperature and the air had been blown out by the first formation of steam, one of the fire-room crew was ordered to go on top of the boiler and close the air cock. This he did, but it appears that he also closed the cock on the outlet leading to the steam gauge so that it failed to register the rapidly forming steam pressure.

No one suspected that anything was wrong with the gauge and the boiler was fired heavily in order to hasten the

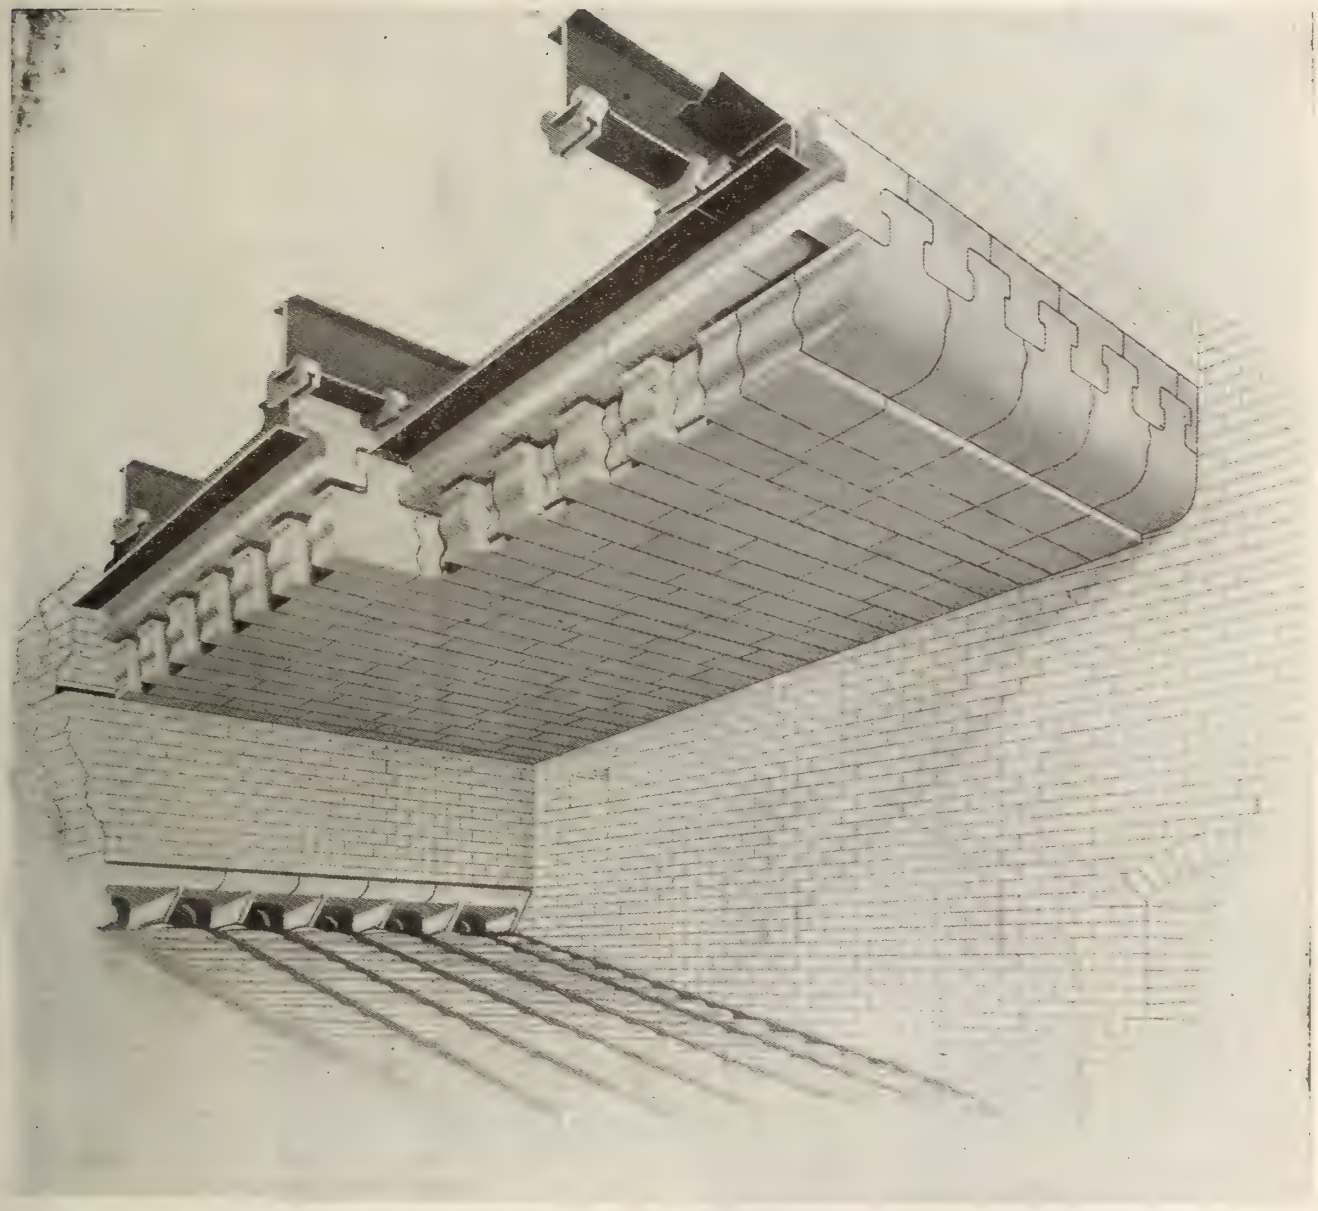
Uniflow or Compound Engines

AN interesting discussion is now going on in the technical press of the Old Country on the question of the relative merits of the uniflow engine as compared with the compound reciprocating engine. The discussion arose from a paper read before the Institute of Mechanical Engineers, and an editorial article in The Engineer, one of the leading English papers. In this article the writer stated that the high efficiency of the uniflow engine was something of a mystery, as there must be a great loss of heat from the large piston which is in contact with steam at practically the condensor pressure while exhaust is taking place, and is then in this cool state brought into contact with steam at admission temperature and pressure when the admission ports open. In a compound expansion engine the differences in admission and exhaust temperatures in each cylinder are very much less, as the uniflow engine has practically the same temperature range in one cylinder that the compound or triple expansion has in two or three. Another point mentioned by the writer of the editorial was that an engine having the high compression that is found in the uniflow engine, and having only a single crank, must be a very difficult engine to start. The writer concluded by giving his opinion that the uniflow engine had practically no advantage over the compound engine. Mr. Perry, the author of the paper, replied to this editorial in a letter, in which he defended the uniflow engine from the objections brought against it. With respect to the cooling effect of the piston, he argues that the cooling effect of the exhaust steam is only felt for 10 per cent. of the outward stroke and 10 per cent. of the inward stroke of the piston, while in the ordinary engine this cooling effect is in evidence for 90 per cent. of the stroke. The high compression which takes place in the uniflow engine, he claims, brings the piston up to the same temperature as the admission steam before admission takes place, thus eliminating condensation from that cause, and as the compression pressure is actually higher than the admission pressure, the steam is admitted into a space already filled with high temperature steam. With regard to the uniflow engine being almost invariably a single crank engine, Mr. Perry claims that this is because the single crank engine is easier to manufacture, and more economical than a two crank engine, and he states that there is no difficulty in starting as the compression can be relieved for this purpose. The question of unequal turning moment, he says, is merely a matter of weight of fly wheel. Thus far the defender of the uniflow type. Then comes Mr. Albert C. Pain, M.I.M.E., of the firm of Belliss & Morcom. Mr. Pain commences by stating that although the uniflow engine is claimed to be more economical than the ordinary compound expansion type, he knows of a case where a uniflow engine was installed in a power plant already equipped with triple expansion engines of the same capacity, and after prolonged tests the uniflow unit was found to require 17 per cent. more coal for the same loads than the triple expansion sets. Mr. Pain claims that it is not a good thing to concentrate all the loads and strains of a large engine on a single crank pin, and a single set of bearings, and a single set of valve motion. He asks if these facts do not account for the trouble often experienced with the bearings of uniflow engines and says it is necessary to flood these bearings with oil from a special pump before starting. He states that he knows of two cases where the metal has been run out of the bearings through neglecting this precaution. The heavy piston also requires a large amount of oil, and the engine generally is heavy on oil consumption. He claims that owing to the heavy piston used, mechanical efficiency of the uniflow engine is less than that of the compound expansion engine. He alludes to the fact that both cylinder and piston of the uniflow engine have to be bored taper on account of the difference in temperatures existing between the centre of the cylinder and the ends. He also claims that they do not stand up so well to high super-heats as the ordinary engine. It can only be built to run at low speeds. Mr. Pain comes to the conclusion that there are so many disadvantages connected with this type of engine that it will eventually disappear. Of course, Mr. Pain is not prejudiced in the favor of the uniflow type of engine by reasons of his business affiliations, and no doubt there will be a reply from Mr. Perry in an attempt to demolish these arguments. There is a good opportunity for those who are interested in this comparative newcomer to the ranks of prime movers to have its pros and cons well discussed by men eminently capable of doing so. It would seem to us that the proposed investigation which a committee of the Institute of Mechanical Engineers are about to make into the uniflow engine from a thermo dynamical and mechanical point should be of great value, and furnish a sound base from which the prospective purchaser of a steam engine can compare the merits of the different types, uniflow, compound expansion, and turbine.

Progress in New Equipment



THE LIPTAK ARCH.

THE LIPTAK ARCH

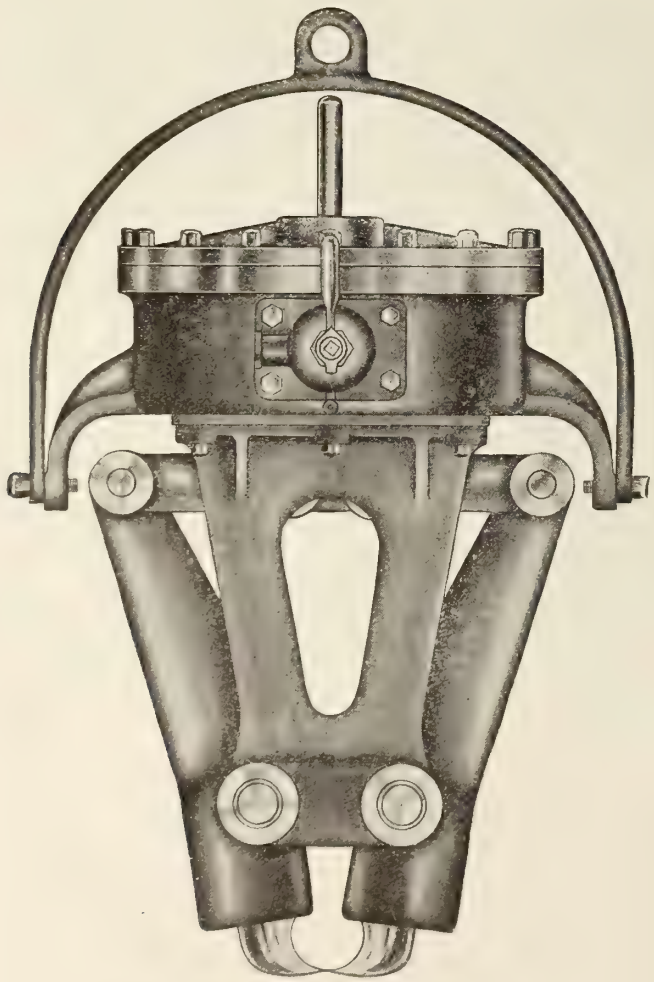
The accompanying cut illustrates the Liptak Arch for boiler furnaces. This is known as the Liptak Double Suspension Arch, and it is claimed that it successfully solves the problem of high upkeep cost of fire arches. A special feature of the arch is the ease with which the framework can be erected, the hangers being hung on the I beams by simply slipping them over as can be seen in the illustration. The T shaped cast channels are then slipped into the hangers, and the whole thing erected without the use of any tools of any kind. On the framework is hung first what is called the emergency arch, which only comes into use when the main arch is completely worn away, and allows the boiler to continue in use until a new main arch can be put in. The reserve arch acts as a protection to the framework, keeping the direct heat of the fire away from it, and therefore prolonging its life indefinitely. It is stated by the makers that crystallization or warping of the ironwork is unknown where the Liptak is used.

The blocks of the main arch, which are in direct contact with the fire, are arranged with staggered joints, which make the flame pursue a broken course, thereby minimizing the destructive action of the fire on the joints. The wave line joint at the ends makes the blocks retain their position until they are com-

pletely destroyed. This form of construction makes the use of fire clay or packing unnecessary, effecting a further saving of labor and material. Dead air spaces are provided between the emergency arch and the framework, and also between the main arch and emergency arch. It is claimed by the makers that a person can stand on top of the arch in bare feet when the furnace is at a high temperature, without suffering any inconvenience. This is a proof of highly efficient insulation. The end blocks are made with replaceable tips, and of special design to afford plenty of support to the apron wall. It is necessary to burn away two arches before the iron work is exposed to the fire. So far the makers have not been called upon to replace any iron work through burning, or to furnish a replaceable tip from the same cause. The Liptak arch is handled in Canada by the Green Economizer Co., Kent Building, Toronto, Ont.

STAYBOLT CUTTER

The Baird Pneumatic Tool Co., Kansas City, have placed on the market the staybolt cutter as shown in the illustration.



GENERAL VIEW OF THE STAY BOLT CUTTER.

It is said that this cutter will clip off staybolts up to 1⅛ in. diameter at the rate of 1,200 per hour.

The machine is composed of a 15 in. air cylinder, the piston head of which connects directly through toggle movement with a pair of lever arms, into which are fastened, but removable, a pair of cutter knives of sufficient strength to clip the stay bolts.

The machine is operated at a working pressure of 100 lbs. air pressure. It delivers 88 tons pressure on the knives and the blades are so designed that when placed against the crown sheet the stay bolt is cut off just the proper distance to allow for heading over.

The machine can be operated on modern rail stay, or marine boilers, and is capable of being held at the gravity point at any angle, being perfectly balanced. This feature allows it to be easily handled on either straight side or radial stay work. Different sized blades are used depending upon the nature and length of bolt to be cut.

The machine is so designed that it can be operated by one man, and all control valves are placed convenient to the operator. Apart from use in staybolt cutting, these machines can be used for the reclamation of scrap. Following are its principal specifications: Diameter of cylinder, 15 in.; travel toggle, 3 in.; maximum capacity between cutter knives, 1⅛ in.; air pressure required, 100 pounds; maximum tonnage on cutters, 88 tons; net weight complete, 430 pounds.

AIR OR STEAM ENGINE

A small engine that may be operated either by steam or air for driving portable mechanism, such as boring bars and drilling machines, has been developed by the H. B. Underwood Corporation, of Philadelphia, Pa. The working parts are inclosed in an oil-tight case which forms part of the engine base. The engine operates at a speed of 250 r.p.m. on a pressure of from 70 to 125 lbs. per square inch. These engines are made in two sizes, 3 and 5 H.P. Weight about 270 lbs.

CYLINDER REAMERS

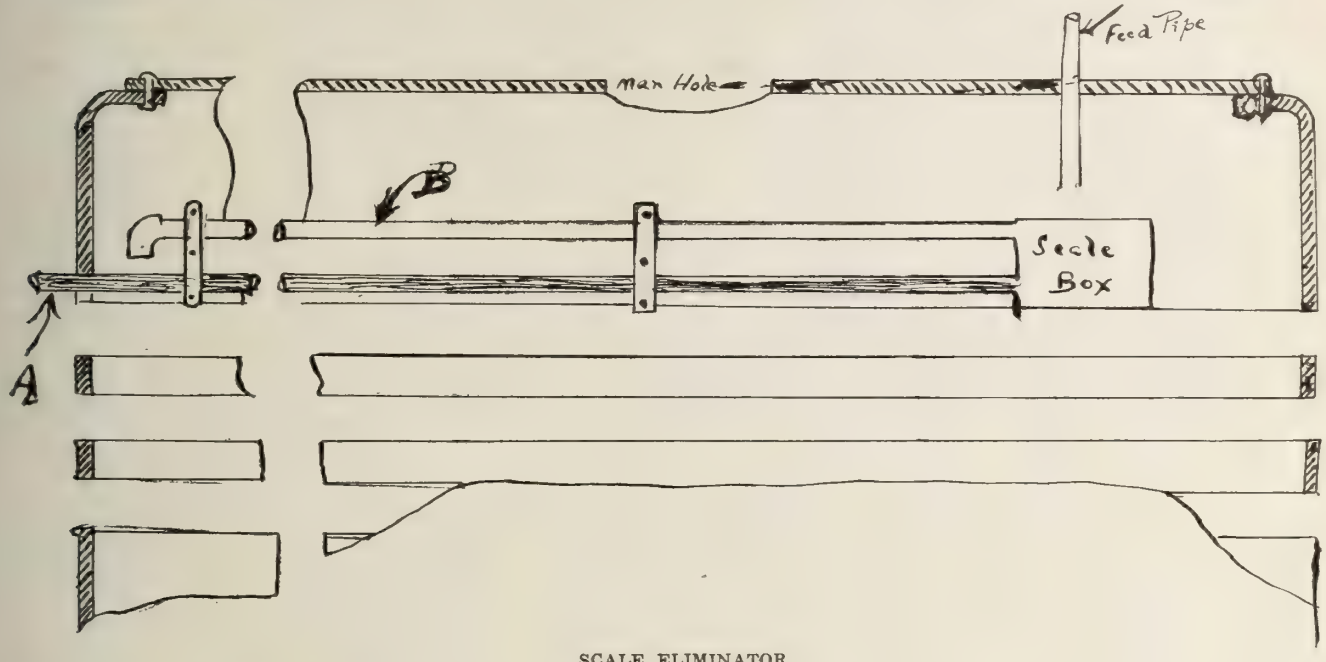
The Wetmore Reamer Company of Milwaukee, Wis., is placing on the market a special set of reamer tools, designed for the production of round, straight and thoroughly smooth holes in small cylinders. A set consists of three reamers, one for roughing, one for semi-finishing and the third for finishing. Suitable arbors are provided for all makes of machines. The finishing reamer is of the floating type. All cutter blades are made of high-speed steel and accurate adjustment is provided to 0.001 inch.

FRICTION CLUTCH

The Link-Belt Company, of Chicago, are now making a new design of "Twycone" friction clutch that embodies the following features:—One-point adjustment, perfect balance, and complete inclosure of all moving parts. The friction cones are lined with thermoid, and the clutch may be operated when running at full speed.

Mr. A. W. Wheatley, who was recently elected president of the Armstrong, Whitworth Co., of Canada, Limited, assumes his new duties well qualified for the position. After serving his apprenticeship with the S. E. Railway in England, Mr. Wheatley went to the United States, where after some fifteen years spent in the mechanical departments of several American railways he was appointed in 1907 to be general inspector of all plants for the American Locomotive Works, with headquarters at Schenectady, N.Y. He was here for only a short time when he came to Canada as manager of the Montreal Locomotive Works, where he remained until 1911 when he became manager of the Dunkirk plant of the American Locomotive Works. In 1912 he returned to Canada as vice-president and general manager of the Canadian Locomotive Company at Kingston, Ont., and continued in this position until 1916 when he was elected to the presidency of the Lima Locomotive Works, Lima, Ohio.

The Operators' Point of View



SCALE ELIMINATOR.

COPPER GASKET KEEPS STEAM ENGINE IN OPERATION

By W. S. STANDIFORD

A number of years ago the writer was roll-turner in a small mill, the roll lathe being driven by a 15-h.p. steam engine. While working on a breakdown job, the rubber gasket on the back end of the steam cylinder gave way allowing the steam to leak out to such an extent that the engine would barely operate the lathe without a tool in it. The writer shut the engine down and looked around the mill for another gasget, or a piece of rubber sheeting to make one, but none could be found.

The mill being located in a very small country town having no hardware store where some rubber sheeting could be gotten, it was necessary to either shut the lathe down until the gasket material could be obtained from a neighboring town, or to use a makeshift to keep the machine running so as to allow the job to be finished, the latter course being decided upon. A sheet of copper 1-32 of an inch thick and of sufficient diameter was found in the shop, and cut into circular shape to fit engine cylinder end, bolt-holes being cut to match those on cylinder. The copper gasket was put on engine when the cylinder was cold; the nuts on the bolts being screwed up as tightly as possible. On starting up the engine, a small wisp of steam issued out in one place, and as the cylinder heated up, the copper expanded and stopped the small leak entirely, thus enabling the turning to be finished with only a small delay. Since then, on other occasions, the writer has also found that two zinc sheets laid on top of one another can also be used in place of rubber gaskets in emergencies and give good satisfaction.

A SCALE ELIMINATOR

In former copies of Power House different methods have been described for feeding water to steam boilers. The inventor of the method shown in the enclosed sketch claims it is among the best ones ever made on the internal feed pipe system. The ordinary scale box is used with the addition of two pipes. The box is located near the front head, from the bottom of the box a pipe extends through the back head and brick-work, a valve is attached and the other end of the pipe from the valve enters the sewer or discharge tank. By opening the valve at intervals most of the sediment will be blown out before it is converted into hard scale. From the top of the box a pipe extends to the back end of the boiler where the water is discharged partly cleared of sediment and practically as hot as the water being used in the boiler. The pipes are held apart by clamps, or pipe B can be lowered to the same level as pipe A by using two 45 degree elbows and a short piece of pipe at the box.

If brass pipes can be used inside the boilers it will be an improvement over iron as scale or sediment is slower in attaching itself to brass than to iron. I am not the originator of this plan. It has been described to me.

JAMES E. NOBLE,
Portsmouth, Ont.

Shipping Documents Must Accompany Goods.—The Customs Department of Australia has notified the Department of Trades and Commerce in Canada that in future, starting from January 1 next, no goods will be delivered unless the shipping documents are on hand. This is because a great deal of trouble has been experienced through the failure of documents to arrive with the goods from Canada. There will be exemptions to this rule only in the most exceptional circumstances, and in these cases an extra duty of 50 per cent. will be demanded pending the arrival of the documents.

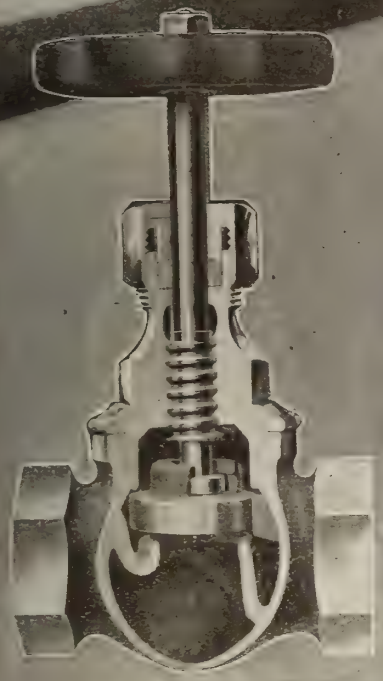
FAIRBANKS-MORSE



An Achievement in Mechanics

EACH individual department of The Canadian Fairbanks-Morse Company, Limited has given industrial Canada a new conception of achievement in mechanics. Each department has established a 100% quality and service standard. This is what enables Fairbanks valves to stand pre-eminent wherever valves are used.

When an engineer specifies Fairbanks valves, he knows that he has selected not only quality of material but workmanship that guarantees perfect operation.

He is satisfied with the reputation and service of the institution that stands behind them. He acknowledges an achievement in mechanics.

Wherever pipe lines are laid—in Canada's great industrial plants—in her immense water systems—in mines and mills—Fairbanks valves are giving a service that is marked by the 100% seal of quality, the standard of The Canadian Fairbanks-Morse Co. Limited.

Our nearest branch will give you the benefit of this service, Our experts will help you in selecting valves and everything mechanical that you require. Make our catalogue your buying guide.

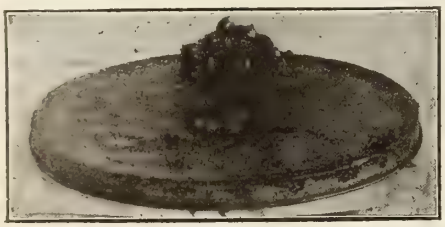
No. 1—Sectional View of Bowser Filter Section Assembled.



No. 2—Filter Disc with dirt filtered from oil.

It Gets The Dirt
It's A BOWSER Oil Filter

The pictures shown illustrate the Bowser Filter Section as used in the Bowser Oil Filter.

No. 1 shows the Filter Section assembled, ready for use. No. 2 shows one of the Filter discs with dirt that the Filter has collected from used oil. This pile of dirt is about 6 in. in diameter and from 2 in. to 3 in. high.

There are twelve of these filter discs and cloths in a Bowser filter section, each as effective as the one you see pictured. As many complete Filter Sections as needed are furnished in the Bowser System.

Bowser Systems are applicable to any size and type of power producing and transmitting machinery.

We will be glad to send literature and explain to you how the Bowser principle of Oil Filtration can be applied to your power plant.

steam pressure which according to the gauge remained at zero. To complete the chain of unfortunate circumstances the safety pressure was permitted to build up and finally the boiler gave way in its weakest part.

The total number of persons killed was 62 and besides this there were 40 more or less severely injured. This unusually large number of casualties for a boiler explosion was, of course, due to the cramped conditions usually prevailing in a ship's power plant and the fact that on naval vessels men are likely to gather in great numbers at any given point, but no doubt the very high pressure at the time was a contributing factor to this large loss of life.—The Locomotive.

WHY WESTINGHOUSE DOES NOT USE THE METRIC SYSTEM

It is sometimes difficult to explain the obvious, all the more so when reasons for explanation appear unnecessary as well as approaching monotonous repetition.

This is doubly true of the case against the adoption of the metric system, whose use pro and con has been expounded in all sections of the United States since the early part of the nineteenth century. At first, suggestions were quietly put forth regarding its supposedly simple characteristics. During the past few years propaganda urging its general adoption has grown more aggressive until now the mails are filled with metric literature. Bills have even been introduced in Congress whose passage would have meant that the use of any system of weights and measures other than metric would have been illegal.

In spite of all this urging there appears to be no general demand for the adoption of the metric system in this country. The manufacturing plants which are using it are few in number and they are doing so under difficulties, while the great mass of people who are responsible alone for a system of weights and measures are scarcely aware of its existence. This cannot be attributed to ignorance for it is taught in all public schools. There is no "gag," for the statutes of the country legalized its use many years ago. If it has so many desired characteristics it would seem to the layman that the process of simplifying weights and measures was very slow.

One of the reasons most commonly urged for the adoption of metric units was that it would greatly aid foreign trade. That would appear to be inviting the mountain to go to Mahomet, for the greater number of manufacturing plants are located in English-speaking countries where naturally the people use only the British system of weights and measures. Factories located in the United States, for instance, sell all but a small per centage of their goods in this country. It would appear then, that to sell a few articles to metric countries, a certain class would make one hundred million people climb out of their accustomed channels to learn a puzzling unfamiliar language. Nor is this necessary, for Westinghouse Electric and Manufacturing Company does a great deal of business with countries using the metric system without difficulty or embarrassment.

From stories sent out it would seem that all foreign countries with the exception of Great Britain were metric. That this is not true is evident from the fact that even those which are out and out metric, like France, Belgium, Denmark, etc., are more familiar with the English system than we are with the metric. In Latin America some countries use a system of English extraction but with Spanish terms. Some use metric and Spanish. Others use metric alone, but they are all familiar with the English.

No one doubts for a moment the tremendous difficulties that would be involved in making this country over into a metric speaking and thinking people. These difficulties would multiply daily until nothing less than chaos would result. First, the greatest number of people in the country would have to learn the metric tables. Then they would have to translate metric terms into English before a ratio of values could be obtained. This in daily life where thousands of small transactions are carried on would be ludicrous. Imagine the mental calisthenics of a grocer should he suddenly be asked for .454 kilograms of butter, which is approximately one pound.

This is a period when production is

DURABLA

STRENGTH—GOODNESS—QUALITY

Performance Facts of Durabla Gasket Material

Tight joints are made and maintained by DURABLA under the following severe services and conditions:

Steam:	275-300 lbs. pressure; 275°-300° superheat.
Oil:	Pressure still joint re-made over 160 times.
Gasoline:	Cylinder heads of gasoline engines and pumps.
Acids:	All acids that can be carried in pipe lines.
Water:	Equally satisfactory with temperature of 40° or 210° F., at any pressure.
Ammonia:	Both absorption and compression systems of refrigeration.
Air:	Air lines and cylinder heads of compressors—all types.

One Standard material for all gasket work—Sold on a Service Basis

DURABLA is sold in sheet or gasket form and the trade mark is stamped all over the material.

Use The LONG STEAM *for* TRAP SATISFACTION

Automatically drains jacket kettles, separators, steam mains. Works against 1 to 200 pounds pressure. Has two outlets and is installed in any position. DOESN'T FREEZE.

The Hamilton Powder Works, Beloeil, P.Q., use them with great success. Read this letter:

Dear Sir: We have used one of your steam traps for a long time and have found the same to answer the purpose as well as any seen in operation. We were so pleased with the working of this steam trap last winter that we ordered six more this season and have fitted them up at various points in the works where live steam is used for heating purposes.

(Signed) J. Murray Wilson,
Superintendent.

Our trap will give you the same satisfaction as recorded above. Investigate and you'll be satisfied, too.

J. T. LONG

4

needed throughout the country, there being a shortage of manufactured materials. Is there any reason for urging the adoption of the metric system at this time, when it is certain that were it suddenly introduced in the factory production undoubtedly would be held up and more than likely would be stopped entirely, until the workmen familiarized themselves with the new units? The very fact that English measurements can be halved and quartered without introducing complicating fractions makes it more advantageous in shop work than the metric measurements.

A case in which metric measurements complicate shop work has been recently acknowledged by an official of one of the largest tire companies in the world. His company recently adopted the metric system and it is now partially used in all except the most recent factory, which is all metric. His words regarding the advantages of the system are interesting, particularly in regard to its use in the storekeeping and shipping departments. In the former, raw materials received in English units must be transferred into metric units by production clerks before going to the workmen. Upon completion, the metric article must again be converted into the English units in order to mark shipping weights. There are some departments of the company which are still using the English system. More translation. This condition, the writer says, will last until the United States adopts the metric system. Judging from past experience there will be a long wait.

NON-CORROSIVE CYLINDER OIL

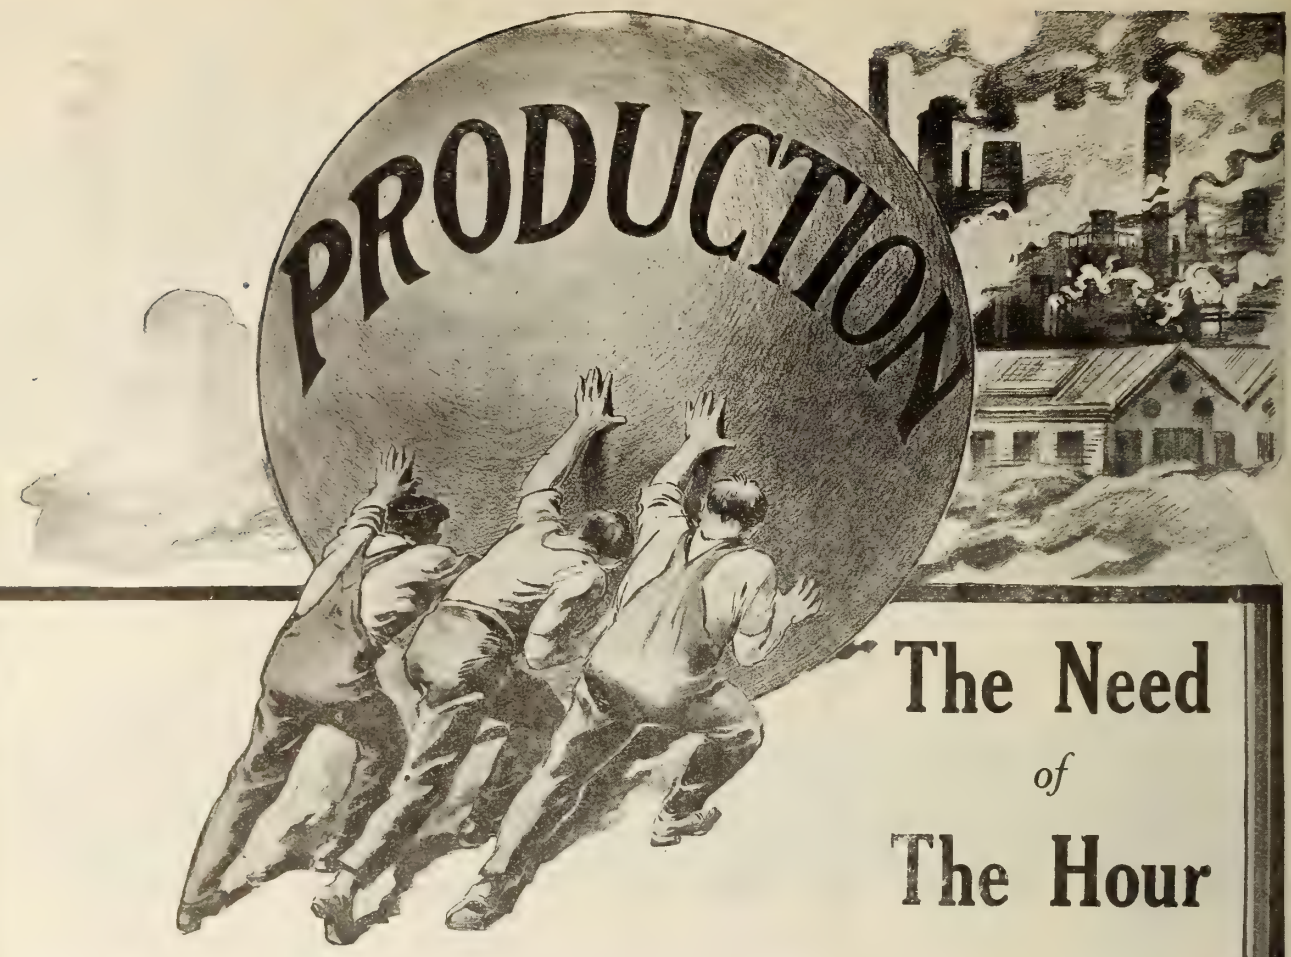
MANUFACTURED ONLY BY E. H. KELLOGG & CO. NOS. 242 TO 244 SOUTH ST. NEW YORK, U.S.A.

FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done—give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

E. H. KELLOGG & CO.,

New York, U.S.A.



The Need *of* The Hour

PUSHING PRODUCTION to meet the demand necessitates the saving of all useless operations about the plant, among which is the constant repacking of piston rods and small valves, which may be avoided by using

"PALMETTO"

REG. TRADE MARK

the packing that has the quality that gives long, satisfactory service.

Such a packing may cost a little more than ordinary packing but is worth it because of the big saving in the labor of frequent application.

Let us send you working samples to test. No charge.

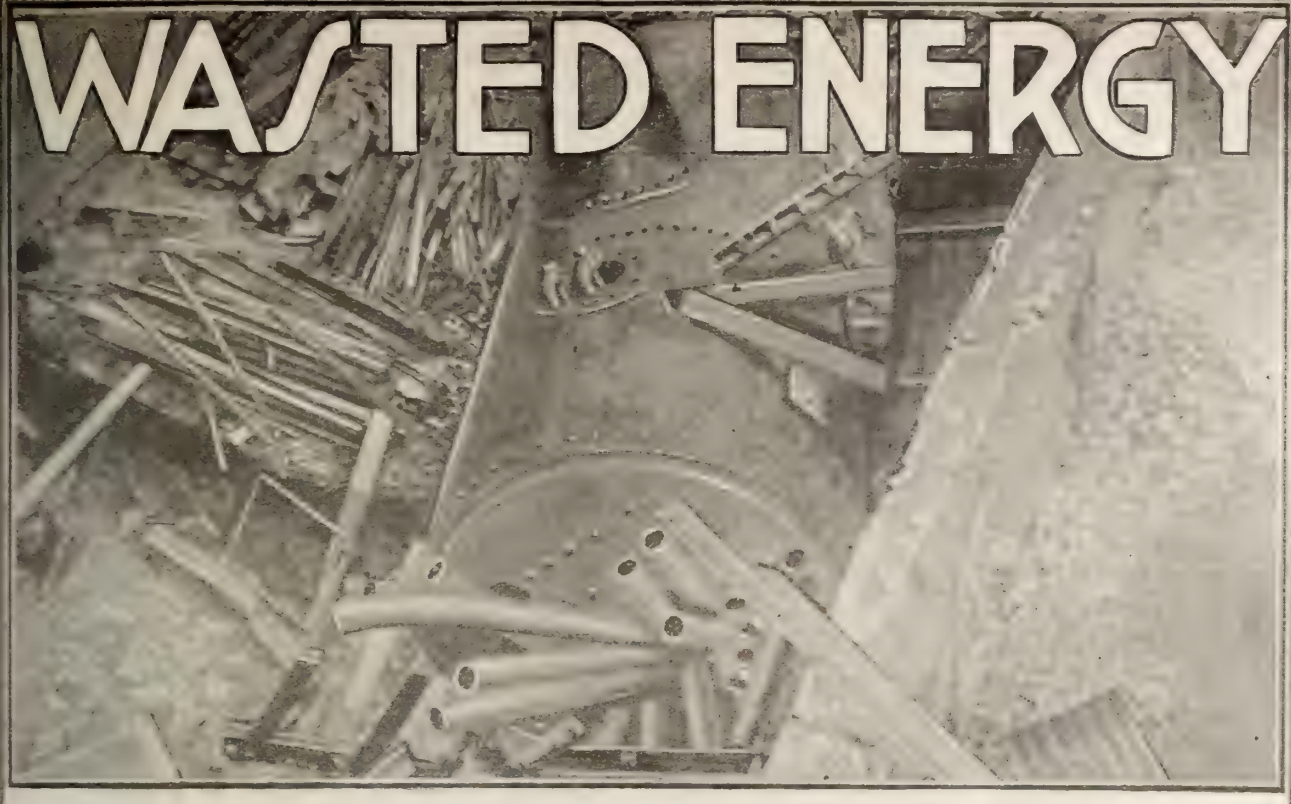
WASTED ENERGY



At first glance, the connection between a boiler explosion and a leaking stuffing-box might not be apparent.

The final result, however, whether by a sudden release of energy, or a slow, steady leak, is the same,—heat energy wasted that would otherwise do useful work on the piston.

A loss that can be avoided by the use of a "live" well lubricated packing, securing a leakless stuffing-box with minimum friction and maintaining a glass-like polish on the rod.

For high pressure and superheat try GARLOCK style No. 446 and "Spare the rod."

Which?

The Old Soft Rubber Valves For Your Plant OR

Rub-Steel Valves

If you are running your plant by obsolete methods; satisfied with makeshifts and second best equipment; content to lose out in the march of progress, the old soft rubber valve is good enough for you.

Voorhees Rub-Steel Valve is the new way, the best way of obtaining real valve service. It cannot soften, dish or blow through the ports. The rigid "backbone" of steel keeps it strong under all temperatures and pressures. The rubber seating surface gives it the necessary resiliency.

Ask for free trial valve.

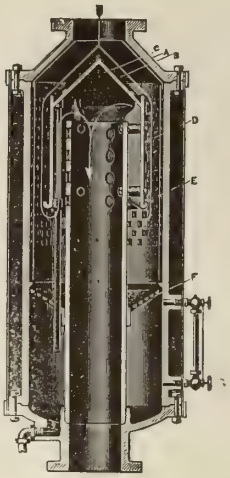
III IMPORTANT THINGS

TO CONSIDER ABOUT A SEPARATOR



I. **THE PLAN**—Is it sensible, will it work, no matter how large the Separator or how well made?

II. **THE SIZE**—Is it big enough regardless of plan, will it hold a good dose of water?

III. **THE CONSTRUCTION**—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

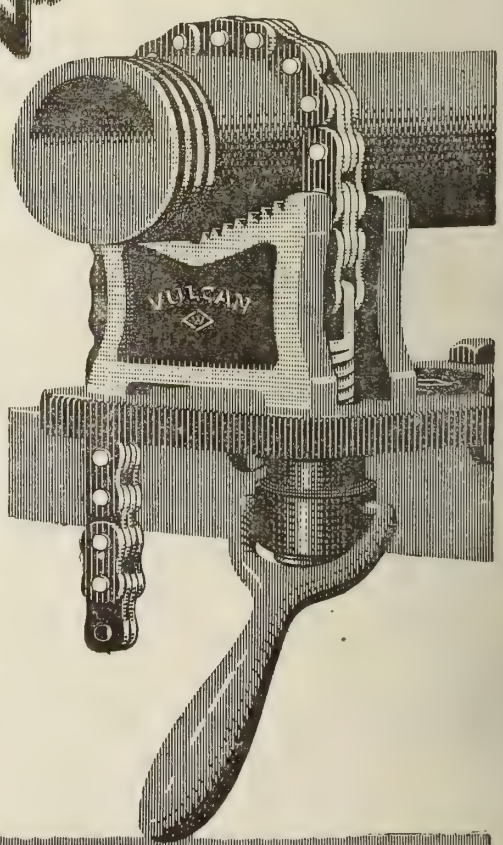
WILLIAMS' "VULCAN" DROP-FORGED CHAIN PIPE VISE



A PIPE vise, like any tool intended for rough usage, should be so designed and constructed that the severe strains and stresses of hard, continuous service cannot cause breakage or failure in operation.

Williams' "Vulcan" Chain Pipe Vises have no weak parts to fail through faulty design. Though they are far lighter and cost less than the conventional cast pipe vise, they are unbreakable. These Vises are made entirely from wrought metal, tested in our Laboratories before used. Each Chain is hand made.

Nothing that engineering experience and technical skill can suggest to improve them is omitted in their manufacture. All are backed by our unconditional guarantee.

Three sizes for ⅛ to 8" pipe. Booklet on request.

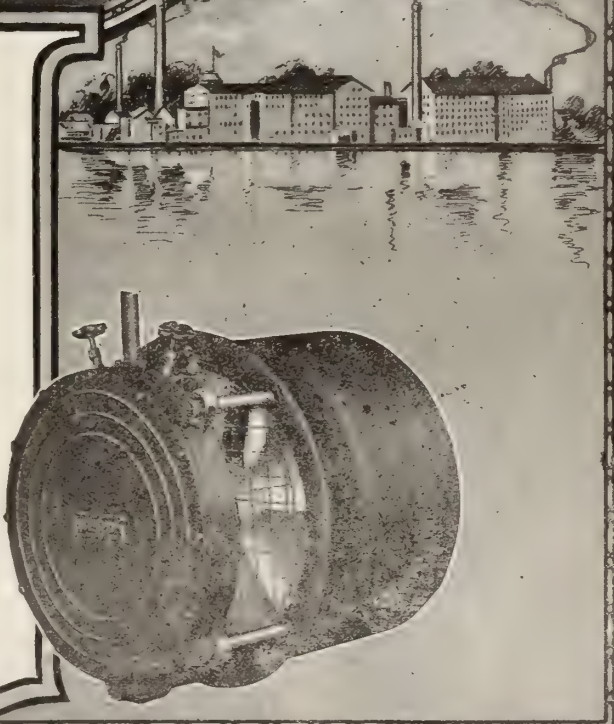
REGISTERED COPPUS U.S.PAT.OFFICE *In Paper Mills*



STEADY steam pressure is a vital factor in making good paper. A sudden drop at the gauge might mean serious loss in the mill. Keeping up steam is a matter of prime importance.

That is why modern paper mills are equipping their power plants with COPPUS Turbo Blowers to maintain constant steam pressure under varying conditions of load, fuel, and weather.

For instance, the COPPUS Blowers shown above operating in the plant of the Hampshire Paper Company, makers of good paper, at South Hadley Falls, Mass., have kept steady steam pressure with very satisfactory results. Peak loads are quickly met, steam pressure is always constant, and cheap fuel is economically burned.

COPPUS Turbo Blowers are helping out engineers and speeding up boilers in power plants the country over. Their good work is not confined to the paper industry—it extends wherever power is used and coal is burned. If they are not already working for you it is likely that they could save time, money and labor in YOUR boiler room.

Write for Blower Catalog.

Clearance Sale of High Grade Technical Books

FOR several years we have maintained a Technical Book Department, handling high-class books published by various well known publishers. For various reasons we have now decided to discontinue our Book Dept. and in order to clear out what stock we have on hand we offer the following books at prices considerably lower than the regular selling price. Each item represents high quality at bargain prices. These books will not last long—first come first served. This is a fine opportunity to add to your technical library.

Title of Book	Name of Author.	Binding	No. of pages	Illustrated	Price
Electric Chemistry	G. W. Cravens	Cloth	132	Yes	$1.10
Hawkins Electric Dictionary (Best)	N. Hawkins	Leather	537	No	2.50

LINCOLN ARC WELDER

Accepted—

THE Lincoln Electric Welding Process is accepted by every class of industry—as being of major importance in maintaining efficient production.

This is because Lincoln Electric Welding saves. It saves hours and days and dollars and cents when a boiler happens to become leaky—or when a batch of castings turns out slightly defective — when a piece of machinery gets broken or worn .

It quickly welds together broken parts — builds up new metal where necessary—and fills molten steel into boiler or other defects.

We will be pleased to discuss Lincoln Electric Welding with you. 'Phone Adelaide 7200 or write us to send a Lincoln Welding Engineer to see you. It costs you nothing for this service.

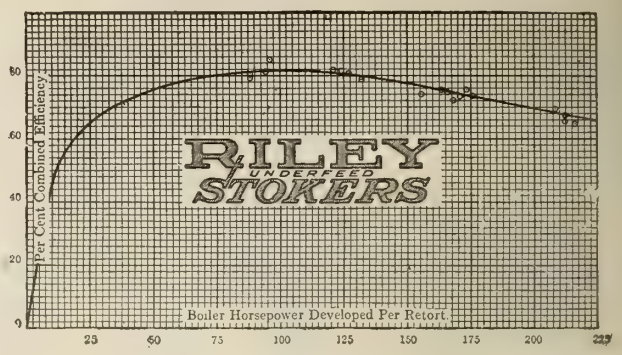
High Efficiency



The continuous high efficiency of the Riley Stoker is due to the moving grates. These moving units not only keep the fuel bed open, porous and free from clinkers, but automatically discharge the ash and refuse.

Because of the moving grates, Riley Stokers have that faculty of operating continuously at high efficiency and capacity. Fuel-saving is a mechanical certainty. There can be no waste.

The efficiency curve shown above is typical of Riley Stoker performance. This curve is plotted from a series of tests conducted on a 16-retort Riley Stoker installed at the Essex Station of the Public Service Electric Company, Newark, N.J. Why not duplicate these results in your plant? You can do it with Riley Stokers.

Riley Stoker catalog HR-8 sent on request.

For information on the Murphy Automatic Furnace for smaller boilers, see last month's advertisement, or send for Murphy catalog HM-8.

Lubrication With Superheated Steam in Reciprocating Engines

The advantages of superheated steam are evidenced by a decrease in fuel consumption, due to increased boiler efficiencies and reductions in steam line losses. These are worth-while advantages. But the vital and important economy of superheat is obtained when the superheated steam is carried *into the engine cylinder.*

The highest returns from superheated steam result from the saving it effects in fuel by the reduction in steam consumption of the engine itself, due to the elimination of cylinder condensation. Only highly superheated steam can accomplish these results. A reciprocating engine will not operate satisfactorily on dry or superheated steam unless lubrication is provided. If it is not necessary to lubricate, it is evidence of moisture in the steam and a lack of superheat.

The ease with which lubrication is correctly applied and the availability of suitable oils are facts which should guide you toward the correct and profitable use of superheated steam.

When you specify Elesco Superheaters, you are assured of the maximum returns from the application of superheated steam. They are designed to suit your conditions.

DEPARTMENT OF LABOUR
Ontario Government

Minister: Hon W. R. Rollo **Deputy Minister: W. A. Riddell, Ph.D.**

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a **Stationary** steam plant of 50 B.H.P. or over, and everyone operating a **Hoisting** steam plant working at a pressure of 20 pounds or over, irrespective of horsepower and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a certificate from the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

All applications should be mailed to the Chairman of the Board. W. C. McGhie, Department of Labour, 15 Queen's Park, Toronto.

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering, the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., ch. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, 15 Queen's Park, Toronto. D. M. Medcalf, Chief Inspector of Steam Boilers.

HOMESTEAD
Quarter-Turn Valves

A Safe and
Economical Combination

The "HOVALCO" Renewable Blow-off Valve and the "HOMESTEAD" Quarter-turn Valve —a money-saving combination designed to give a clear passage and be absolutely tight when closed, consequently leak-proof!

Homestead Valves are made in Straightway, Threeway and Fourway patterns

The special alloy seats and discs of the Hovalco can be reversed, reground or renewed without shutting down the boilers.

KERR

("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

TRIMO

THE WORD TRIMO

Stands for good tools made by the Trimont Mfg. Co., which are the following:—

The Trimo Pipe Wrench
The Trimo Chain Pipe-Wrench
The Trimo Monkey Wrench
The Trimo Pipe Cutter (Hand)

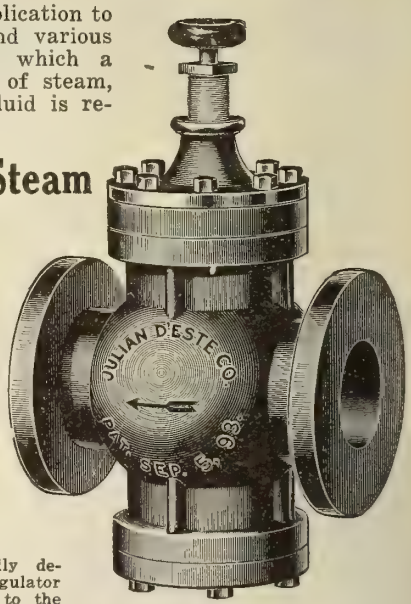
The four good points that make **Trimo Pipe Wrenches** superior are the **Spiral Spring** always in place—**Steel Frames** that will not break—**Nut Guards** that protect adjustment nut — and the **Inserted Jaw** in handle that can be replaced when worn—**Save Money** and buy Trimo goods, made by

Trimont Mfg. Company
Roxbury (Boston,) Mass., U.S.A.

CURTIS Engineering Specialties

Universality!

For universal application to all the varied and various conditions under which a reduced pressure of steam, water or other fluid is required the



Improved Steam Pressure Regulator

has no equal.
It is compact and self-contained, without levers, weights or projections.
No glands or packing; no drip for leak of steam or water. Suitable for any boiler pressure; made entirely of metal: is a lock valve, very simple and sensitive.
Send for leaflet fully descriptive of this Regulator (contains price list) to the manufacturers.

Canadian funds are accepted at par at Montreal.

Make Our Engineers Responsible for Your Belting Equipment

Put it up to them to place your transmission equipment on a 100 per cent. efficiency basis; make recommendations that will create savings, which in turn will practically offset any expenditure they may suggest.

So certain are we that our belting experts can practically eliminate your transmission troubles, we are quite willing to analyze your plant at no cost to you.

Practically every plant has one or more drives that are hard on belts. Just such drives as these are now equipped with

Dominion Friction Surface Belting

which for fifty years has justified every claim by satisfactory performance.

When you have belt trouble, phone, wire or write our nearest service branch.

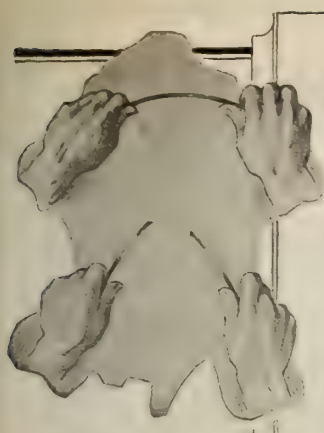
IN THE STEAM PLANT.



broken blades are not always poor blades.

Often it's a case of a good saw used in the wrong way. A hack saw may be brittle as glass or flexible as a watch spring, according to the temper of steel, but the temper is only one of the things that go to make good blades.

Starrett Hack Saws are tempered, milled and selected according to the work they are designed to do. That's why they "cut quicker and last longer."

According to the Starrett system of blade selection, there's a saw for every metal. Many saws will cut more than one metal, but no single blade will cut all metals, or even all shapes of the same metal economically.

Starrett Hack Saws plus the Starret Hack Saw Chart make it easier to cut metal economically. Ask for a copy of Chart CD—and "Hack Saws and Their Use"—both are free.

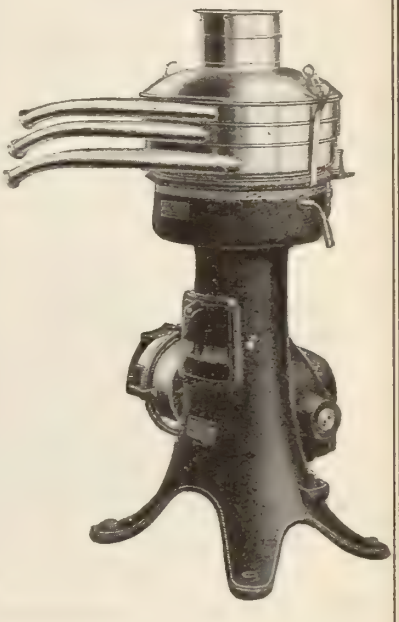
De Laval Oil Purifiers Save Oil and Add Years to Life of Machinery



The De Laval method of purifying used lubricating oil is quicker, more efficient, and more economical than any method of purification previously used.

It reduces the loss of power due to friction, eliminates the danger of clogged oiling systems and lengthens the life of machinery by maintaining clean oil in the oiling system indefinitely. In a number of cases it has been found that the temperature of the oil is reduced by the De Laval method of purification.

By the De Laval method the used oil may be purified continuously or in batches. By either system the purification is complete and is accomplished instantaneously. All foreign matter such as water, grit and particles of metal are removed in the bowl of the purifier and the oil is returned to the lubricating system as good as new.

The De Laval Oil Purifier occupies less than two square feet of floor space, requires less than two h.p. to drive, and needs very little attention. The bowl is the only part that requires cleaning, and this is done without muss or waste of oil—quickly and easily.

De Laval engineers will be glad to investigate conditions in your plant and to recommend the type of installation best suited to meet them.

Write to nearest De Laval office for Oil Purification Bulletin No. 100; also Crank Case Oil Bulletin No. 102.

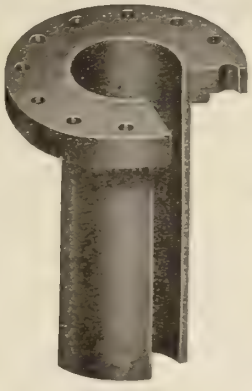
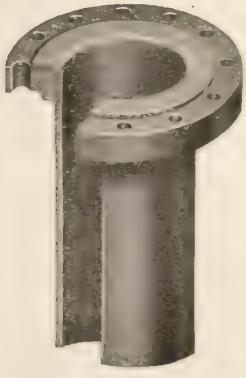
P⊗H FLANGED PIPE JOINTS



SCREWED



P.H. LAP

P⊗H LAP FLANGES, for any service, have proven to be the best yet designed, and they have many advantages over other styles. The pipe is not weakened by cutting into the wall as when using screwed flanges. The gasket bears on the face of the lap and absolutely prevents leakage through the bore of the flange. The hub of the flange is bored slightly larger than the outside diameter of the pipe so that the flange will swivel readily and accommodate itself to any slight variation in the position of the bolt holes, an advantage which is obvious to the fitter and eliminates torsional strains in attaching.

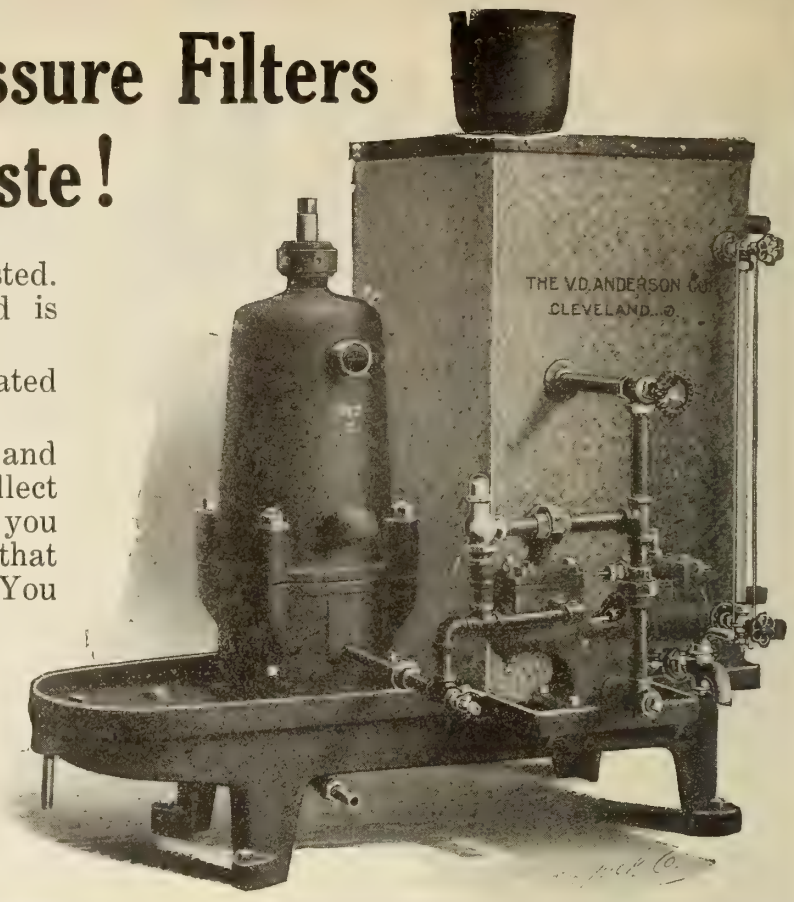
Anderson's Pressure Filters Prevent Oil Waste!

Oil is too high in price to be wasted. Yet more than half the oil used is wasted—lost on wipers.

The Anderson Filter here illustrated will **prevent** this dead loss.

Place drip pans beneath engines and machinery. Pass the oil you collect through the Anderson Filter and you will have oil as pure and clean as that which is fresh from the refiners. You can use the oil over and over again; always the Anderson makes it as clean as before!

We shall be glad to furnish full particulars.



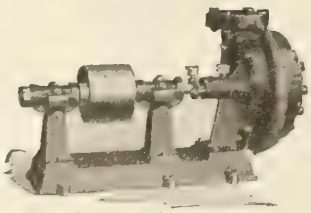
The V. D. Anderson Co.
West 96th Street, Cleveland, Ohio

AMERICAN-MARSH PUMPS

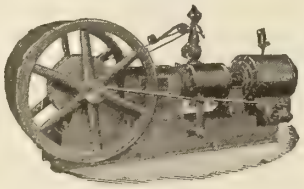
SIMPLE **RELIABLE** **EFFICIENT**

The American-Marsh steam pump is an improved form of the famous Marsh Pump which has been on the market for over thirty years, during which time over 150,000 have been manufactured and sold.

The American-Marsh Pump has no internal stuffing boxes, no tappets and no slide valves. The auxiliary valve is of the semi-rotative disc type of an improved design. The main steam valve is of the balanced piston pattern, assuring highest efficiency. The water ends have large valve areas and are fully bronze fitted, including solid bronze piston rods and bronze removable water cylinder bushings.



American-Marsh Centrifugal Pumps are made with the same high grade of material and workmanship which characterizes the construction of the steam pumps. They are made in all sizes up to 12 inch, both single and two stage for heads up to 250 feet.



The line also includes—

Power Pumps
Deep Well Engines
Air Compressors

Jet Condensers
Dry Vacuum Pumps
Boiler Feed Pumps

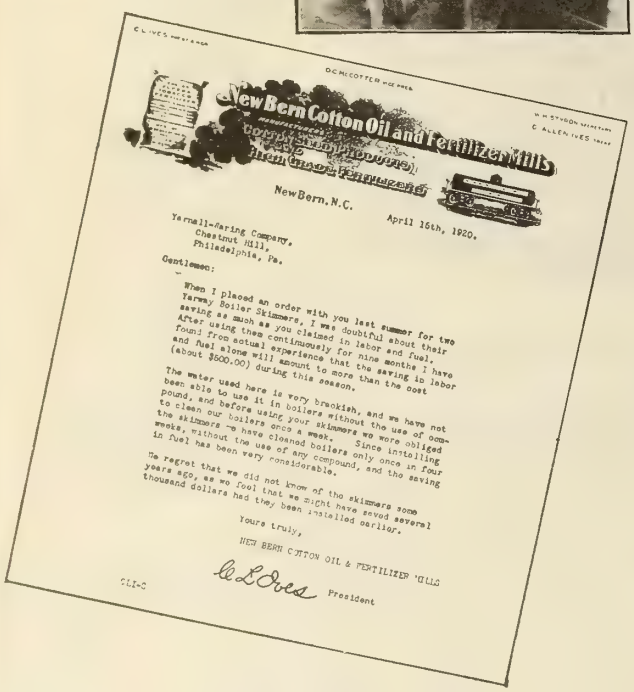
Yarway Skimmer installed on Boiler No. 1, New Bern Cotton Oil & Fertilizer Mills, New Bern, N. C.

Yarway Skimmer installed on Boiler No. 2, New Bern Cotton Oil & Fertilizer Mills New Bern, N. C.



New Bern Cotton Oil and Fertilizer Mills

New Bern, N.C. April 16th, 1920.

Yarnall-Waring Company,
Chestnut Hill,
Philadelphia, Pa.

Gentlemen:

When I placed an order with you last summer for two Yarway Boiler Skimmers, I was doubtful about their saving as much as you claimed in labor and fuel. After using them continuously for nine months I have found from actual experience that the saving in labor and fuel alone will amount to more than the cost (about $600.00) during this season.

The water used here is very brackish, and we have not been able to use it in boilers without the use of compound, and before using your skimmers we were obliged to clean our boilers once a week. Since installing the skimmers we have cleaned boilers only once in four weeks, without the use of any compound, and the saving in fuel has been very considerable.

We regret that we did not know of the skimmers some years ago, as we feel that we might have saved several thousand dollars had they been installed earlier.

Yours truly,
NEW BERN COTTON OIL & FERTILIZER MILLS
W L Ives President

ECONOMY *renewable* FUSES

Double Protection for Electrically Driven Machinery

Knife-blade type

The "Und. Lab. Inspected" label on Economy Fuses and the symbol on Economy "Drop Out" Renewal Links mean double protection for all industries using electrical energy.

Factory inspection is backed by constant rigid tests in the Underwriters' Laboratories.

Economy Fuses are accurately rated. They give maximum safety and efficiency at minimum cost—cut annual fuse maintenance costs 80% as compared with the use of "one-time" fuses.

Fibre cartridge, sturdy end-caps and the vinged washers which securely lock the fuses are virtually indestructible.

Ferrule type

All that is discarded in a blown Economy Fuse is the inexpensive strip of fused metal, which is replaced in a few moments by a new Economy "Drop Out" Renewal Link.

For sale by all leading electrical jobbers and dealers.

Economy Fuse & Mfg. Co. of Canada, Ltd.
UNITY BLDG. MONTREAL, CANADA

Economy Fuses were the first line using an inexpensive bare link for restoring a blown fuse to its original efficiency to be APPROVED IN ALL CAPACITIES by the Underwriters' Laboratories.

Dirty Boiler Tubes Spell W-a-s-t-e

Soot and ash deposits on the tubes of a boiler inevitably mean wasteful operation—lost coal, low boiler efficiency.
They probably also indicate the presence of other boiler and engine room losses—for failure to remove soot deposits is generally symptomatic—the power plant operator who ignores dirty boiler tubes will ignore other causes of waste.
If you want to keep up steam when soot piles up in your boiler, you will have to pile in more coal.
Diamond Soot Blowers are the one logical solution to the soot problem. Last year 2,200,000 H.P. of boilers were equipped with Diamonds. For the first six months of 1920 the record is 1,500,000 H.P.
As compared to the best possible results with the hand lance, Diamonds will effect the following economies:

1. FUEL: a saving of 5 to 8%.
2. BOILER EFFICIENCY: an increase of 4%.
3. LABOR: a saving of many hours per day.
4. LONGEVITY: an increase in the length of service of boiler tubes through the prevention of corrosion.
5. STEAM: a saving of 25 to 75% of steam used for cleaning.

If your boilers are not yet equipped with this money-saving apparatus, ask for Bulletin 280.

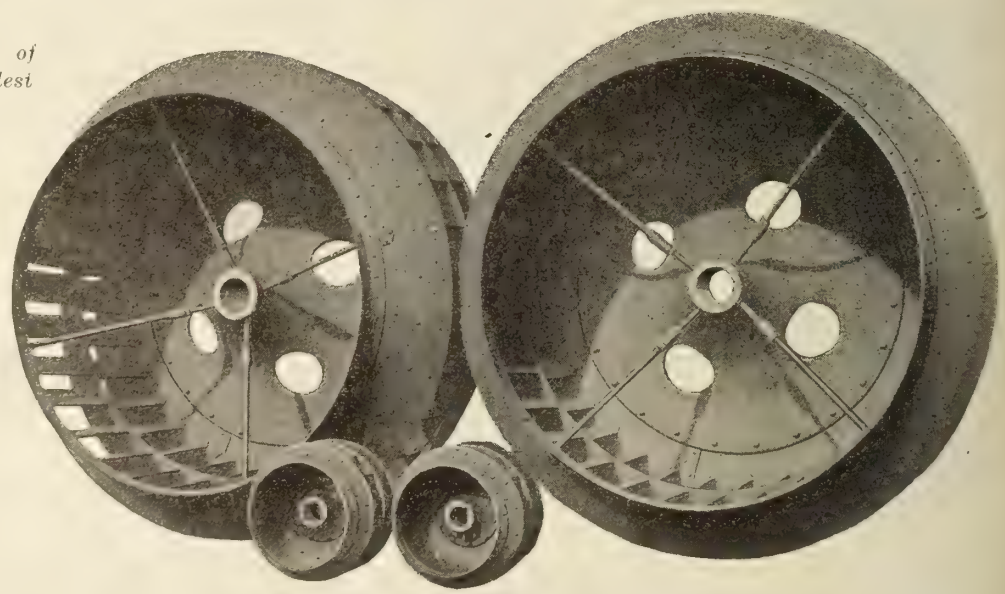
SOOT BLOWERS - SAVE 4 to 8% FUEL

Comparison in Size of the Largest and Smallest Fans Manufactured



More Draft for Less Power

GREEN'S RADIAL FLOW FANS are built for capacities of 1,600 to 275,000 cubic feet per minute and pressures up to 7 in. of water.
These fans, besides having low horsepower requirements, operate at the most economical speeds for direct connection to turbines and motors, making possible small high speed efficient units.
Fans are built in two types—"RB" and "RR"—for forced and induced draft, respectively.
Our Engineers will be glad to submit data covering the requirements of your individual draft problem. Let us send full details.

Hose Built to *Modern* Specifications

MOST equipment of fifty years ago has little place in modern industrial plants. Improved methods are constantly needed to keep pace with modern standards of production and efficiency.

Yet until Goodyear entered the hose field, rubber hose was built in much the same old-fashioned manner as it had always been.

But Goodyear went into the foundry, the mine, the paper mill, the railway, the steel plant—studied the *actual* conditions industrial hose must meet in use.

Then new standards were set. A *better* hose was developed to meet the demands of modern industry.

The cover on ordinary water hose was found inadequate to protect it against the sharp objects over which it is constantly dragged. In a great many cases this cover was cut through and the hose destroyed long before it had given the service it should.

To prevent this, Goodyear Water Hose is fitted with a thicker-than-usual cover of exceptionally tough rubber. A cover that prevents wear and gives longer life to the hose.

Added to the good inner tube and strong fabric, it explains why Goodyear Water Hose has set a new standard for economy and freedom from hose troubles.

The efficient construction and unusual economy of Goodyear Water Hose is characteristic of all Goodyear Industrial Hose.

A man trained by Goodyear in hose problems will call upon you without obligation. Phone, wire, or write the nearest branch.

Which!--One-Piece or Thousands?

Joints cause the failure of fire brick linings. The front wall and door arches are usually the weakest points in a laid-up fire brick lining. A lasting arch cannot be built of separate fire brick with its many joints filled with fire clay. The joints soon open enough to allow the bricks to separate or drop out, thus weakening the arch and paving the way for a total collapse.

The one-piece lining is the logical fire brick lining, because there are no separate bricks and clay joints.

Betson's Plastic Fire Brick

because af its make-up and the experience behind it, has made the one-piece lining a practical possibility and success. With this material the door arches and firebox walls are formed in one solid block, from the grate lining to the boiler shell and up around the sides of the smoke box on fire tube boilers, or up to the tube headers on water tube boilers. The entire construction is self-supporting and requires no iron door or other reinforcements. The front walls fit the boiler shell perfectly.

Betson Plastic Fire Brick costs less to install and will outlast the ordinary fire brick lining several times over.

Write for informing pamphlet on boiler furnace linings.

Belliss & Morcom Engines at Verdun, P.Q., Waterworks

Belliss & Morcom Engines Were Chosen By The City Engineers At Verdun, P.Q.

When an engineer selects an Engine or Air Compressor you can rest assured that it is the best in its class for the particular job for which it has been chosen. No detail escapes his attention; design, operation, manufacture and maintenance are thoroughly investigated and tested. That's why you'll find Belliss & Morcom Engines and Air Compressors in many of Canada's most modern engine rooms. Their scientific principles and design and their long service records stamp them as the best in their class and they are the invariable choice of engineers and men who know. When you're in the market, do not fail to investigate the Belliss & Morcom line.

We carry a complete line of Power House Equipment and Supplies. Prompt shipments from stock assured. Complete Power Plants designed, erected and equipped. **Enquiries cheerfully answered.**

Dependable Service Means Real Economy

For carrying service from wrought-iron or light-weight mains—thru threaded connections that insure dependable service—there is nothing equal to

MUELLER Service Clamps

The straps are all hand-forged, soft steel—with threads and nuts accurately cut. The malleable clamps are galvanized by the hot process, which fills all pores and prevents leaks.

Write for catalog and prices. Mail orders given immediate attention.

H. MUELLER MFG. CO., LIMITED, SARNIA, ONT.

WORTHINGTON-SNOW
OIL ENGINE

See our exhibit at the

SIXTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES

Grand Central Palace, New York

Week of September 20th

Other Worthington Products:

Steam, Power, Centrifugal and Water Works Pumps. Meters, Oil Engines, Condensing Machinery, Air Compressors, Vacuum Pumps and Water Wheels.

To further enlarge their service, Worthington have acquired the good-will and mechanical equipment of the Platt Iron Works, Dayton, Ohio, for manufacturing Oil Mill Machinery, Hydraulic Turbines, Feedwater Heaters and High Pressure Air Compressors.

Horse Power Hours at $34

CAN you do it with coal at $15 the ton? Not so. Not even with old man Economy himself stoking the fires.

But you can buy your horse power hours at about $34 using Worthington-Snow Oil Engine prime mover service. For the Worthington-Snow Oil Engine is a horizontal, full diesel engine. And the diesel engine is the most economical prime mover yet designed. The main feature of the Worthington-Snow Engine is its economy—the percentage of potential power actually obtained for useful work.

Even when boilers are oil fired Worthington-Snow Oil Engines will deliver cheaper horse power hours. Computing costs on the basis of prevailing fuel prices, coal costs about $50 the horse power hour, fuel oil $43. Either way you figure it, Worthington-Snow Oil Engine is a well-paying investment.

DUMP THE MATERIAL WHERE YOU WANT IT WITH A—*Jeffrey Travelling Tripper.*

—and you will be surprised how easily and accurately you can control the handling of loose materials in your power plant.
The Jeffrey Travelling Tripper, has assured a method of emptying the buckets, has its cams made of thick wearing surface, deep chilled, and hard as flint—may be lowered and quickly shifted when carrier is idle or a stationary tripper is in service—is so easily balanced that it can be readily moved when Carrier is in motion—and its release ends are adjustable for easy release of the buckets.

Simple, safe, accurate, and mobile it possesses all the characteristics that go to make up other Jeffrey equipment.

Our engineers will gladly point out to you all the advantages of the JEFFREY Carrier. Write to-day for our new Catalog No. 210.

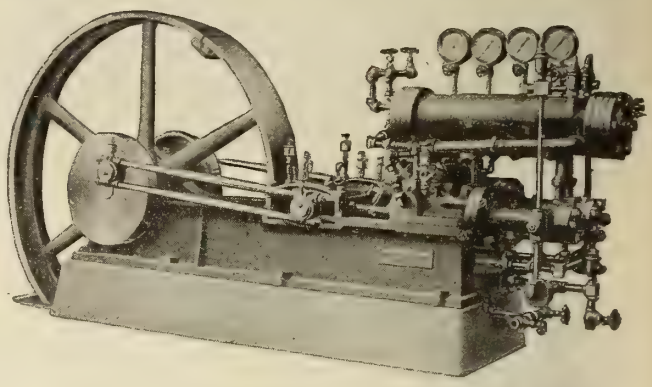
NORWALK
AIR & GAS · COMPRESSORS

The Norwalk Record

of unvarying success in foundry compressing service has been maintained under severe and widely differing operating conditions. Whatever the individual problem of the user may be, it is part of the Norwalk job to solve it.



NORWALK FOUR-STAGE, BELT-DRIVEN AIR COMPRESSOR

For air-line efficiency, start right by using Norwalk Compressors.
"Norwalks always do the work."

WORTHINGTON POT VALVE
BOILER FEED PUMP

The throbbing heart of industry

DOWN in the depths of boiler rooms the world over, Worthington boiler feed pumps are successfully satisfying most exacting service demands. Functioning perfectly and without falter, they are the throbbing heart of industry.

Since 1840, Worthington power plant apparatus has satisfied over 200,000,000 boiler horse power. Of this line of apparatus, Worthington Pot Valve Boiler Feed Pump is a worthy representative. It is regularly built for pressure up to 300 pounds. Where space is limited the pump can be furnished with center-packed pot valve water end.

In addition to boiler feeders, Worthington manufacture a most complete line of pumps and pumping machinery which has earned for the Worthington line the title of "world's standard."

Other Worthington Products:

Steam, Power, Centrifugal and Water Works Pumps. Meters, Oil Engines, Condensing Machinery, Air Compressors, Vacuum Pumps and Water Wheels.

To further enlarge their service, Worthington have acquired the good-will and mechanical equipment of the Platt Iron Works, Dayton, Ohio, for manufacturing Oil Mill Machinery, Hydraulic Turbines, Feedwater Heaters and High Pressure Air Compressors.

Chicago Pneumatic Class O-CSC Air Compressor installed by the Continental Motors Corporation, Detroit, Mich. Capacity 1538 cubic feet of air per minute

Try inhaling through your fist

VACUUM resistance means wasted power! Breathing through your fist requires effort —wasted effort.

In an air compressor, pulling against a vacuum due to a choked intake is *wasted power.*

With Chicago Pneumatic Air Compressors it's different—

Their unloading system automatically holds the inlet valves open after unloading. This permits free passage of air at no load.

If your compressor is working against a vacuum, a Chicago Pneumatic will save power at every stroke.

This is *one* Chicago Pneumatic feature. It will pay you to know *all* of them. Bulletins upon request.

Proper Lubrication Pays

TROUBLE with plant machinery usually simmers right down to a problem of correct lubrication. Hasn't that been your experience time and again?

The *right* lubricating oil for every working part is your best insurance of smooth running, effective mechanical units—which, in turn, means full-capacity plant operation.

Engineers who have standardized on Imperial Lubricants find the quality uniform with a grade especially suited for every type of machine. And *immediate* supplies are always available in any quantity.

Imperial Lubrication Engineers co-operate with plant engineers and superintendents to get more work out of power-producing and power-using equipment at lower lubrication costs. An experienced Imperial Oil man will gladly make recommendations for the particular needs of your plant.

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.**

BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

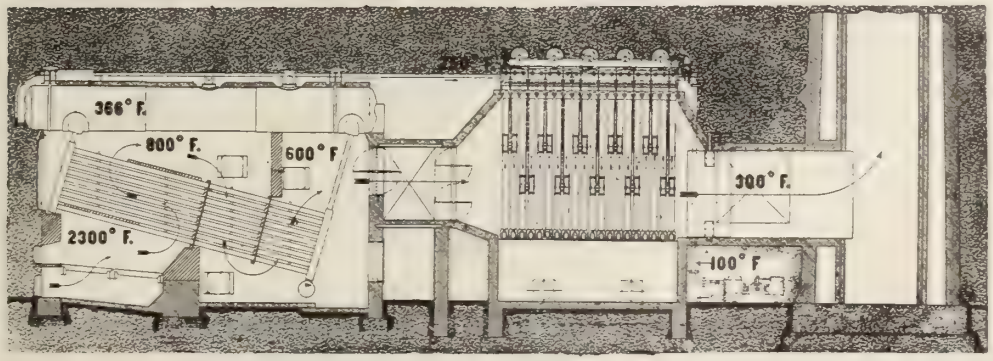
GREEN'S ECONOMISERS



A Saving of 13.6%

Green's Economiser "installation temperature diagram," showing a rise of 150° in feed water temperature above that of the feed water heated. This is not an unusual case, and under these conditions would show a saving of 13.6% based on 1% saving for each 11° increase in feed water temperature.

Modern economic operation of boiler plants demands that your boilers be operated above normal rating. This means higher exit temperatures of the flue gases.

Green's Fuel Economisers utilize this heat in the flue gases to heat the feed water under boiler pressure, which accounts for the fuel saving and also allows you greater boiler capacity.

Ask our engineers for data on economisers for your plant.

GREEN'S ECONOMISER, LTD.
TORONTO

Another New Link-Belt Data Book

Enables you to select Roller Chain Drives for Industrial Drives,—Tractor and Truck Drives

FOR years the power transmission engineer had his Link-Belt Silent Chain Data Book, which enabled him to select the correct silent chain drive for his purpose and figure its cost. This is the recognized authority on silent chain drive practice.

And now comes this new hand-book of roller chain practice. It shows how to figure drives, determine prices, gives information on care and upkeep, and a wealth of other information on this whole subject which will prove invaluable to the engineer and others interested in roller chain.

The subject of wheels is also gone into very thoroughly. (The chain is the standard and the wheels must be made to fit it, to assure their working together properly.)

In short it is a complete handbook of roller chain application and design. It is not merely a catalog.

Send for it today. Use the coupon.

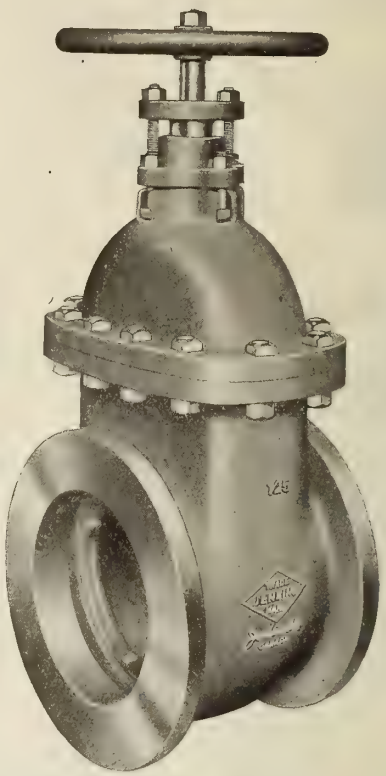
A DEPENDABLE VALVE FOR EVERY PURPOSE

The Valve Test That Safeguards A 56 Years' Reputation

We might well depend solely upon the care used in their designing and the high-grade materials from which they are made to maintain the high standard of value established by Jenkins Valves some 56 years ago.



—but that our enviable reputation may be preserved unimpaired we see to it that every valve bearing our well-known Diamond Trade-Mark is **thoroughly tested before leaving the plant.**

So that the valve purchaser who specifies Jenkins Valves is insured against the losses inherent with the cheap imitations of the genuine Jenkins, a host of which is now on the market.

Therefore—look for the Diamond Trade-Mark on the body of the valves you buy. It is your guarantee of long and satisfactory service, even where conditions of usage are more than ordinarily severe.

Stocks at all good dealers.

The Design of Moore Steam Turbines Prevents Steam Leaks

Ample surfaces at the joints have been provided to prevent leakage of steam—also the number of vertical joints have been reduced to a minimum. In a turbine having numerous vertical joints it is almost impossible to prevent leakage and consequent loss of efficiency in operation.

The careful designing to prevent all steam leakage is but one feature of Moore Steam Turbines. Send for our booklet. It explains fully the others.

Moore Steam Turbine Corporation

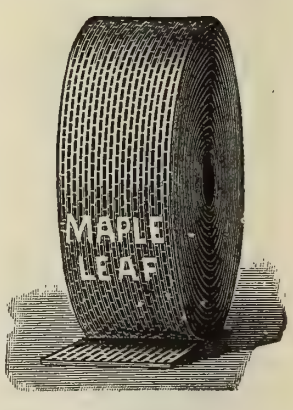
Wellsville New York U.S.A.

Dominion Belting Company, Limited Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

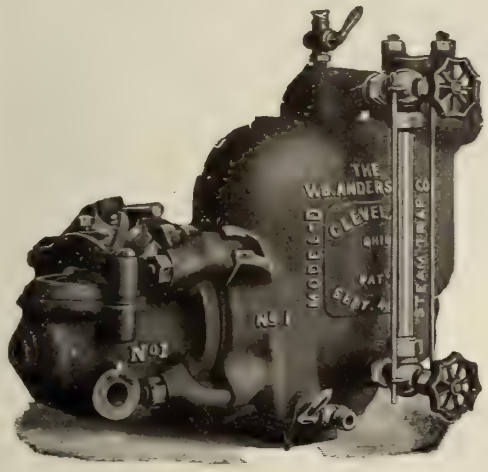
Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

DOMINION BELTING CO. Ltd., Hamilton, Canada-Quebec Branch: 51 Duluth Bldg., Montreal

THE ANDERSON Model "D" STEAM TRAP



Tight from the day you put it in!!

Think of the care-free trap service you will have once the Anderson is in your steam room! Tight from the moment it is installed!

The Anderson Model "D" Steam Trap is operated by a counter-balanced Lake Superior Copper Float. Its large area valve is always under deep water seal, and it will never wire draw.

Every part is machined to solid gauges. The self-contained strainer and self-contained by-pass are Anderson features. The simple design gives complete accessibility to every part.

Write for full particulars.

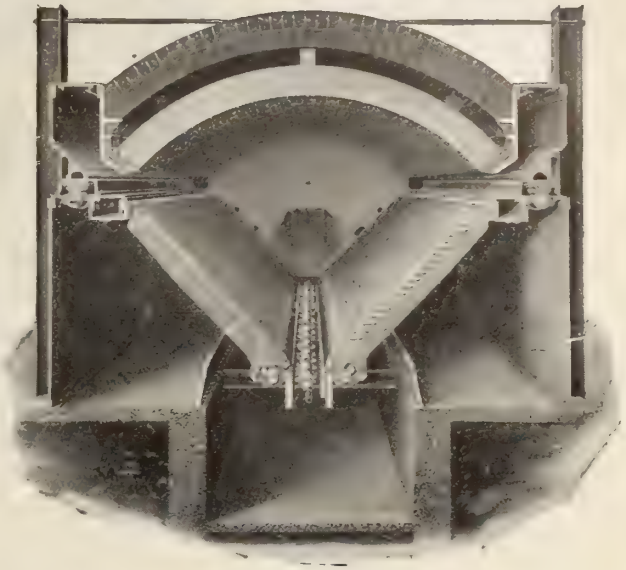
1935 W. 96th St., CLEVELAND, Ohio.

MURPHY AUTOMATIC FURNACES



For Any Boiler

50 h.p. and Up

Any boiler from 50 h.p. and up can be equipped with the MURPHY FURNACE. The *smaller plant* can therefore enjoy all the economical advantages of fuel and labor savings *without resorting* to forced draft.

To-day over 6,000 *boilers* are fired by MURPHY FURNACES. You will find them used in nearly every branch of the industry—from hospital to industrial and central station service. MURPHY FURNACES "burn any fuel that has heat in it." They double the output of the plant "without one penny for draft."

Our Catalogue "CM-9" shows how MURPHY FURNACES can be installed under any type of boiler—50 h.p. and up.

For information on RILEY UNDERFEED STOKERS for large boilers, see last month's advertisement or send for RILEY STOKER Catalogue "CR-9"

GENUINE BRITISH-OAK TANNED

LEATHER BELTING

TRADE MARK

The Oak Leaf is the Sign to Go By

Bear in mind the Oak Leaf—the sign of dependability—the next time you buy belting; it will serve you as a guide to better belting service in your plant.

Three features loom large in the manufacture of D. K. McLaren's Leather Belting. They are: **The Hide, The Tanning and The Workmanship.**

THE HIDES are cut from the **backs** of the choicest steers.

THE TANNING. Genuine British Oak Tanning imparts that desirable toughness to the leather for which D. K. McLaren's Belting is famous.

THE WORKMANSHIP is of the highest grade possible.

Altogether, if you make sure that the Oak Leaf is on your next belting, you'll secure exceptional service.

Two Types of Jones Under-Feed Stokers

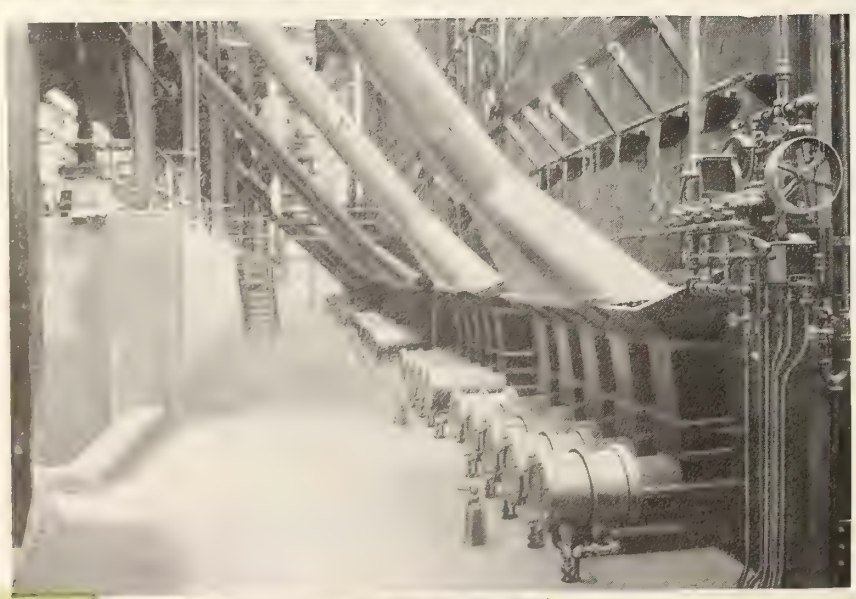
"A-C" and "STANDARD"

Jones "A-C"

Jones "A-C" Stokers

are automatically cleaned, high-duty stokers. From coal-hopper to ash discharge the cleaning is entirely automatic. No hand labor is needed. No trouble is experienced from big clinkers in the fire—and no clinkers are formed either on the bridge wall or side walls.

As the steam-driven rams push the charges of green coal into the retorts, the entire fuel bed is slowly pushed toward a balanced dump plate at the rear. This is ***not*** a gravity movement. The incline of the retorts is not sufficient to to cause avalanching. By the time the fuel bed reaches the rear of the furnace, the fire is burned out and nothing is deposited on the dump plate but dead ash and refuse. This dump plate is so balanced that it is easily and quickly operated by hand. No power driven dumping mechanism to cause trouble.



Jones "STANDARD"

Jones "Standard" Stokers

are very simple. There are no moving parts in the fire—and very few moving parts of any kind. Simplicity and easy accessibility insure low maintenance costs.

Fuel and air supplies for both types of Jones Stokers are controlled automatically, and proportioned for complete combustion and high efficiency with any grade of coal. Smoke is waste—with Jones Stokers there is no waste. The automatic controls can be adjusted to maintain any desired steam pressure within very close limits—regardless of sudden changes in load.

Jones "Standard" Stokers can be installed under limited space conditions. No ash pits or other excavations are necessary. Old boilers can be equipped without changing settings. Wherever installed, they increase fuel efficiency and reduce operating and maintenance costs.

Jones Service

The engineering department of this company will be glad to give assistance in the handling of any power plant plans involving the possible use of stoker equipment. As the oldest manufacturers of the under-feed type of stokers, our experience enables us to solve unusual combustion problems, either in the power plant field or for special purposes.

We have prepared a catalog illustrating and describing the Jones "A-C" Stoker and another one showing the Jones "Standard" Stoker in detail. We shall be glad to mail a copy of either or both of these books to any interested engineer.

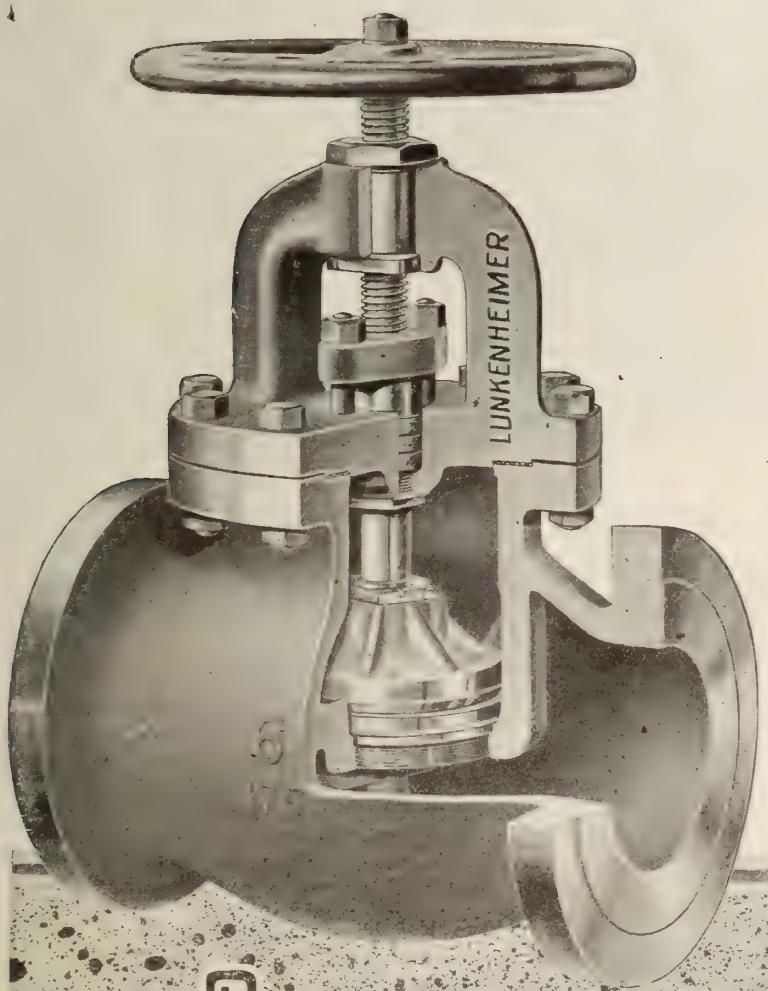
-lasting satisfaction

LUNKENHEIMER

IRON BODY BRONZE MOUNTED

GLOBE, ANGLE, CROSS & CHECK VALVES



give lasting satisfaction in service. Their design, extreme strength and durability due to the high quality materials used, and the Lunkenheimer system of test and inspection which they undergo, insure safety and maximum valve service.

Lunkenheimer "Valve-iron" is close grained and has a tensile strength far in excess of the iron used in the average valve. The trimmings are made of Lunkenheimer "Valve-bronze," a material possessing extreme wear resisting qualities.

The compensating seat in Lunkenheimer Valves will adapt itself to any slight distortion which may be caused by temperature change or pipe strains. The seating surfaces are re-grindable and all the parts renewable.

For high temperature service these valves can be supplied with trimmings made of Lunkenheimer "Valve-nickel"

All standard sizes, in three weights, for working steam pressures up to 125, 175 and 250 pounds.

Specify LUNKENHEIMER Iron Body Valves and insist on their installation.

Some Recent Utilization of Water Power

Some Facts From a Paper Read Before the Institute of Mechanical Engineers, Great Britain, Which Illustrate Development in this Apparatus.

By ERIC M. BERGSTROM

IN THE years 1890-1898 a power station was erected at Chevres, near Geneva. It consisted of 15 Jonval turbines of the multiple-runner type, each having an output of 1,200 h.p. under a maximum head of 26.5 ft, and at a speed of first 80 r.p.m. and then 120 r.p.m. In its day, which was not so long ago, this plant was representative of the highest stage of hydraulic engineering as it existed. If this plant were built today and equipped with high-capacity Francis turbines, a single-runner turbine at 120 r.p.m. would give an output per unit of 2500 h.p., or, conversely, with an output of 1200 b.h.p. the maximum speed would be approximately 175 r.p.m., which would mean a very material saving in the cost of the electrical-generator equipment. With each unit consisting of a double Francis turbine, a maximum output of 5000 b.h.p. would be secured at a speed of 120 r.p.m., or with the original output of 1,000 b.h.p. a speed of 290 r.p.m. would be obtained.

To present the recent advances and the present state of water-turbine development was the purpose of the paper recently presented before the Institute of Mechanical Engineers (Great Britain), by Eric M. Bergstrom, from which the above facts are taken.

Under the heading of Francis turbines Mr. Bergstrom calls attention to the early development of standard turbines which could be sold at an exceedingly low cost. This was followed by an increase in size of units specially designed for the conditions of installation which gave considerably greater economies than could be realized from standard machines. Following this development came the recognition of the value of "specific speed," which many leading manufacturers now use as the basis for the manufacture of standard runners, a series of runners corresponding to a certain specific speed being selected as standards to meet the conditions most frequently met with.

The important factor in connection with modern turbine practice is that exhaustive tests have been made giving a complete knowledge of the efficiency and other characteristics of each standard wheel made, so that knowledge of its behavior under varying conditions will enable a runner to be selected which will meet most efficiently a given set of requirements. The standardization of the modern turbine has been developed from these improved methods of systematic tests which provide definite knowledge of the chief characteristics of the turbine. The early American standardization practice was empirical in nature and did not encourage further developments.

It is a general practice for European turbine manufacturers to install testing plants within their own works. This enables them to accurately analyze not only standard runners, but any new special designs. The importance of tests of research work has best been shown by the evolution of the Francis runner, the development of which has been possible by exhaustive trials and intelligent applications of the results obtained.

The development of the high-capacity runner has enabled designers to use a higher value of specific speed during the last ten years. Where the limit of specific speed was approximately 75 (330 metric system) in 1909, today turbines have been installed with a specific speed of approximately 95 with good efficiencies resulting. It is now possible to obtain runners of specific speed of 100, together with even a higher maximum efficiency than secured previously with a specific speed of lower value and with only small sacrifice in efficiency at part gate.

A design of runner recently constructed by the Escher Wyss and Co. gave good results at speeds corresponding to a specific speed of from 85 to 112. The main feature of this new turbine, shown in Fig. 1, is the large space be-

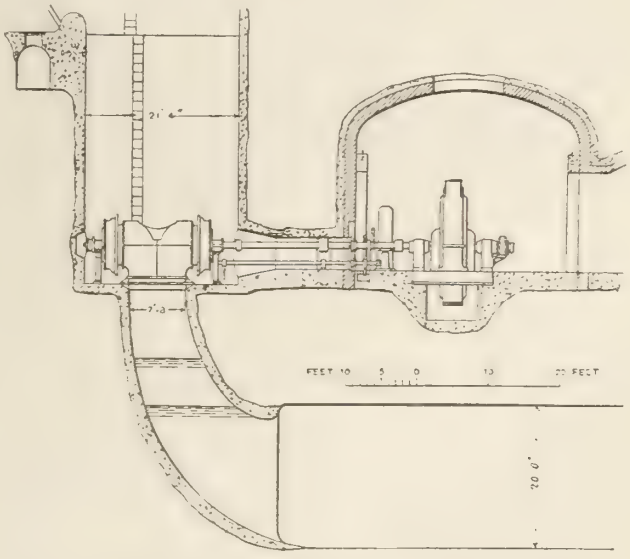

FIG. 2—HYDRO-ELECTRIC POWER STATION AT FORSHULTEN, SWEDEN.

tween the guide vanes and the entrance edge of the runner.

Two examples of notably high efficiencies are given; the American installation at the Appalachian Power Co. with a 6,000-h.p. single open vertical unit operating under a 49-ft. head at 116 r.p.m., specific speed 69.5, with an overall efficiency of 93.7 per cent.; the Forsse Hydroelectric Plant, Sweden, with a 3,750-h.p. double enclosed horizontal unit, operating under a 57-ft. head at 250 r.p.m., specific speed 80, giving a maximum overall efficiency of 94 per cent. Other efficiencies ranging from 87 per cent. up are given of plants installed in Norway, Switzerland, Canada and the United States.

It follows logically that these most notable achievements in maximum efficiencies are the results of the more careful and correct runner design referred to before. Improvements in the design of casing, guide apparatus, suction casings and suction tubes are based on a better understanding of the conditions of flow in various parts of the turbine, thus eliminating as far as possible impact losses and eddy losses in the water during its passage through the turbine.

Another significant fact is the long range of gate openings for which an efficiency of over 80 per cent. is obtained. In 1911 results of experiments were published showing the average efficiency of tests then on record to be 85 per cent. This value has been greatly exceeded, and a general increase of 10 per cent. above efficiencies obtained twelve years ago can now be recorded.

The low-pressure Francis turbines used for heads up to 75 ft. are in Europe generally located in open flumes to which the water is conducted through an intake channel, the plant being arranged with vertical or horizontal shaft. The American arrangement for this class of turbine is generally a single vertical turbine, and the most notable developments in hydro-electric plants have been with this type of runner.

The power plant at Forshulten, Sweden (Fig. 2) is an example of a typical horizontal low-pressure turbine plant. The units, of which there are six in operation, each with an output of 3,000 h.p., are arranged with double runners on a horizontal shaft. They operate at 187 r.p.m. under a net fall of 42.6 ft., the wheels being placed in open concrete pits protected by sluice and strainer racks, the two runners discharging into a common cast-iron suction casing. The shaft is supported at each runner on two outside ring-lubricated bearings, in addition to a babbit-lined automatically grease-lubricated bearing inside the suction casing. The practice of providing the turbines with lignum-vitae underwater bearings has now been discontinued in favor of outside ring oil-lubricated bearings, the bearing on the inlet side being made accessible through an inspection tunnel as in the present case or through a vertical steel funnel protruding above high-water mark.

More than usual interest is presented by the arrangement adopted at Mockfjaerden Hydroelectric Power Station, Sweden, on account of the power house being situated underground and using open turbines under the relatively high fall of 72 ft. The arrangement of the plant is seen from Fig. 3, and comprises four units each having an output of 5,000 b.h.p. at 225 r.p.m. with double runners on horizontal shafts. Each turbine is placed at the bottom of a concrete-lined shaft and discharges into the common tailrace tunnel. The power house is blasted out of solid rock, the floor level being approximately 70 ft. below the surface, whereas the switchboard and transformer are housed in a separate building on ground level and communicate with the power house below through an inclined shaft. The alternators are directly connected to the turbine shaft and, due to the underground situation, special arrangements had to be made to insure sufficient cooling. For this purpose the alternators are totally enclosed and cool air is forced down a separate shaft and distributed through underground ducts to each alternator, the hot air escaping from the top of the housing and being expelled through the vertical shaft communicating with the surface.

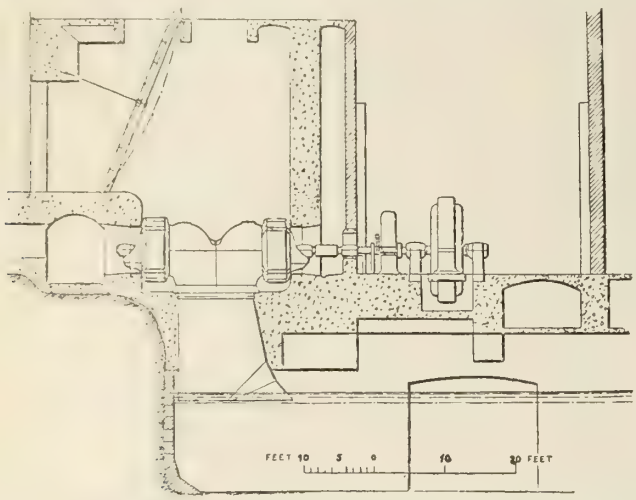

FIG. 3—MOCKFJAERDEN HYDRO-ELECTRIC POWER STATION, SWEDEN.

Medium-pressure Francis turbines are classified by the author as those operating between the heads of 75 to 150 ft. A unique installation of this type of turbine is the Porjus Power Station, Sweden. As in the case of the Mockfjaerden Power Station, this plant is also situated underground, but the turbines are enclosed in steel casings and placed at the bottom of the intake shafts about 160 feet below ground level. The vertical shafts are cut through solid rock and provided with liners of steel pipes with an internal diameter of 11 ft. 6 in.; and with flanged connection to the turbine casing. There are five units with an average capacity of 12,500 hp. each under a net fall of 163 ft. running at 225 r.p.m. The turbines are of the double type with two runners, discharging into the common suction casing. The power house is also blasted out of solid rock, and is 36 ft. wide and 310 ft. long, communicating with the turbine chambers through the short tunnels which accommodate the shaft extension connecting turbines and alternators.

The roof is supported on a strong concrete arch, and by the provision of false walls and roofs leaving a space between the rock and the walls through which warm exhaust air from the generator is allowed to pass, all damp is prevented from penetrating into the power house. The generators have a normal output of 11,000 kva. and 10,000 to 11,000 volts 3-phase current. The necessary switchgear and transformers are also in this case placed in a separate building on ground level, a shaft providing communication between this building and the power house below, through which the heavy parts of the machinery can be lowered; in addition to which there is lift accommodation both for passengers and goods. The line voltage is 80,000, the power being utilized for railway traction and for mining purposes.

As an instructive example of the arrangement of the medium-pressure turbine with horizontal shaft and spiral casing, Fig. 4 shows a section through a unit of the Massaboden Hydroelectric plant used in connection with the Simplon Tunnel in Switzerland. Each unit is capable of developing 3,500 b.h.p. under a net head of 142 ft. at 500 r.p.m. The turbine is equipped with two runners cast back to back in one piece, the outside bearing being arranged with thrust collars to take up any unbalanced thrust in an axial direction.

The noteworthy fact with medium-pressure plants as in the case of low-pressure turbines is that recent developments seem to favor single-runner units on account of higher mechanical overall efficiency and less foundation work, coupled with lower initial cost. The decision in each case must be made on its own merits and with a careful

consideration of local conditions.

The outstanding feature in the development of the high-pressure Francis turbine is its adoption for use with increasing heads. Today Francis turbines utilizing a head of from 500 to 600 ft. are not uncommon, the highest fall for which a Francis turbine has been designed being approximately 745 ft.

The most important improvement in the Pelton wheel is in the system of regulation which was necessary for new conditions of electrical transmission, and the demand for accurate and reliable automatic governing. The inherent defect of the method of by-pass regulation being liability to stick and excessive wear, together with difficulty of insuring synchronizing action, resulted in the introduction of the deflecting nozzle. In recent years the combined spear and deflecting nozzle has come to the front and has now been adopted in most modern plants. A number of different designs of this method of operation can be traced to one of the three systems shown diagrammatically in Fig. 5. In each case the operating cylinder of the oil-pressure governor operates the deflector and spear simultaneously when opening, but by sudden closing of the governor the

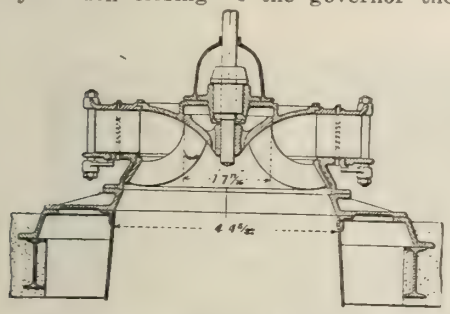

FIG. 1—NEW TYPE OF TURBINE BUILT BY ESCHER, WYSS & CO.

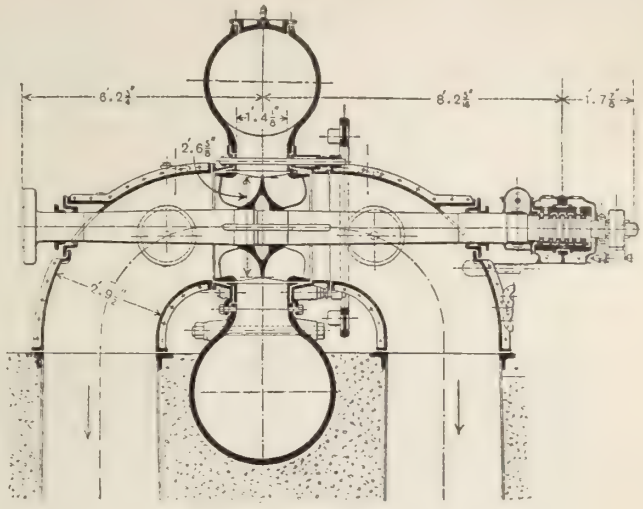
deflector will in the first instance cut into the jet and divert the water from the wheel until the spear, by slowly overcoming the dashpot resistance, regulates the water supply corresponding to the load, when the deflector will be brought back into a position just tangential to the reduced jet. The free movement of the deflector, independent of the spear in the closing direction, is in each case permitted by the "lost motion" existing in the mechanical connection between the deflector and spear.

The principal development in the design of pipe lines has been the use of concrete for low-pressure lines where its low initial cost and durability give it a decided field of usefulness. In some places concrete pipes have been used as a pressure line when a special form of reinforcement and treatment to exclude leakage has been adopted. Wood-stave pipe line is of value because of its durability, low cost, and low coefficient of friction, and is therefore of practical advantage for the construction of the upper portion of pipe lines where suitable wood can be procured.

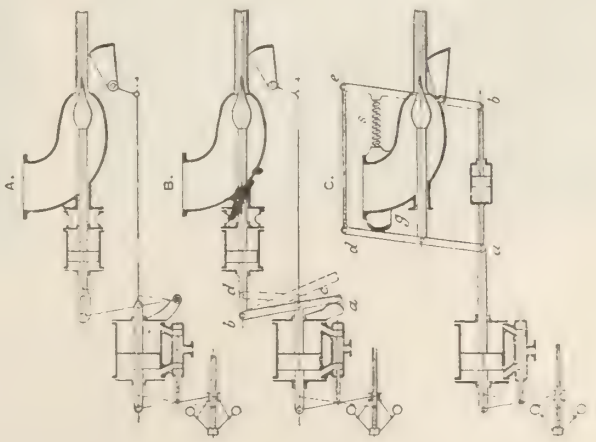
The welded-steel pipe lines signify the most important developments in recent years because of the progressive utilization of high heads requiring close study of pipe-line construction. Welded pipe lines are exclusively used for high-pressure installations on account of their



superior strength and absence of rivets which obstruct the flow of water. Welded pipes are heated by means of water gas and welded under high-speed, mechanically-driven hammers, which produce a weld of approximately 95 to 97 per cent. of the strength of the full plate. After welding the pipes are annealed to remove all internal stresses. The foregoing process is only suitable for material up to about 1¼ in. thick, as above this thickness the heat would not penetrate sufficiently to produce a uniform welding heat. For larger plate thickness, the "wedge-welding" method is resorted to, the edges being brought together and a separate bar inserted, forming the weld. With this method pipes up to a thickness of 1¾ in. can be satisfactorily welded. The material used in welded pipe lines is best open-hearth steel, with a tensile strength of 56,000 lb. per sq. in. and an elongation of 20 to 25 per cent. in 8 in. On account of pressure surges plate thicknesses are calculated with a factor of safety of from 4 to 5, based on the strength of the weld equal to 100 per cent. Pipes are made in lengths of an average of 18 to 20 ft., using riveted joints for medium pressures and flange or expansion joints for high pressures. In the riveted, or so-called "bump" joint, the pipe ends are swelled so that the rivet heads do not obstruct the free area of the pipe.

A further improvement in the art of welding is reinforced welded pipe, consisting of a number of solid forged rings shrunk on to the outside of the pipe and adding further strength to the pipe with a reduction of plate thickness. This innovation in pipe design permits, for high heads, the use of a larger-diameter pipe without exceeding the maximum limit of plate thickness to obtain a reliable weld. thus reducing the number of pipe lines for large installations and the initial cost of installation. Although the present method of manufacture permits only short lengths of reinforced pipe to be made, these may be welded together with a circumferential weld into lengths of about 18 ft. In high heads this method of pipe-line construction makes an appreciable reduction in the initial cost of the development.

In his conclusion, Mr. Bergstrom shows the results of an estimate of the available horsepower in the principal countries of Europe and America. In the United States 28,100,000 h.p. are shown as available, 24.9 per cent. of which has been developed; 2,000,000 in



Switzerland, of which 25.5 per cent. has been developed; 4,000,000 in Italy, of which 24.4 per cent. has been developed. Lowest percentages of development have been in Great Britain, with 8.3 per cent. of 963,300 h.p.; Spain, with 8.8 per cent. of 5,000,000 h.p., and Austria-Hungary, with 8.8 per cent. of 6,460,000 h.p. These figures apply, as stated above, only to Europe and the United States of America, and do not include the vast resources in white coal of Australia, Asia, Africa and the South American continent. An Interesting Instance of Oxy-Acetylene Welding

Conditions in the Building of the Ohio State Fair

ALTHOUGH practically every job undertaken by a welding shop represents a saving of time, labor and money, it is not until some particularly large job comes along that the value of oxy-acetylene welding is driven home with a punch.

One of these large jobs, the execution of which resulted in an imposing saving, was recently undertaken by the Imperial Welding Company of Minneapolis, Minn.

The machinery to be repaired was the fractured high and low pressure cylinders of a 1,000 H.P. compound steam engine employed to furnish power for a flour mill. The damage occurred through the piston rod fracturing close to the cross head and the pistons driving through the ends of the high and low pressure cylinders. The fractures in the low pressure cylinder are shown in figure 1. The crack in the upper left hand corner of the picture extended back to and completely around the inlet valve port. The crack at the bottom of this cylinder extended no further than can be seen in the photograph.

As the casting was preheated the men in Figure 1 could not, of course, have worked from the position shown. They are so shown in the picture to give an idea of the size of the cylinder bore.

The high pressure cylinder, which is indicated at the right of Figure 3, was also badly broken, as the welded section shows.

Inasmuch as the engine was of an obsolete type and occupied excessive space in the engine room, upon a report of the accident the owners decided they would replace it by a steam turbine. However, when the matter was taken up with the manufacturers it was found that no delivery date could be promised within ten months. This delay was, of course, out of the question, no outside power being available.

Then an effort was made to obtain the old patterns from the firm that had originally made the cylinder. Here again the flour mill owners met with disappointment. The original patterns had been destroyed, and new castings would have cost approximately $9,000 exclusive of freight charge and cost of installation.

The location of the engine room and adjacent machinery was such that the cost of installation would have reached a high figure and would have brought the entire bill, exclusive of the costs of delay, up to approximately $15,000.

Having failed to obtain a steam turbine and not caring to spend such a large amount for new castings, the owners at this point took the matter up with the Imperial Welding Company and asked if the cylinders could be satisfactorily welded. Upon being assured that they could, the job of reclamation was given to the Imperial Shop and men were set to work at once to repair the damage.

Four men were employed to do the work, the actual time to weld the castings being forty-eight hours. The total amount of time to chip out the castings and otherwise prepare for welding, as well as to actually make the welds, was three weeks. The operation presented no unusual difficulties, preheating being done one section at a time.

The material used for the work consisted of the following: 30 cylinders Airco oxygen, 26 cylinders Airco acetylene, 4 pounds flux, 407 pounds cast iron rod, 4,150 pounds charcoal, 32 carbon blocks ½x6x12 inches. An Airco "A" welding torch was used to do the work

The actual cost of welding these cylinders was $1,572.22. Not taking into consideration the delay that would have resulted if new castings had been made, the owners were able to save over $13,000 by taking advantage of the oxy-acetylene process.—Acetylene Journal.

Points to Observe in Purchasing Equipment

In This Lecture, Delivered as One of the J. F. Aldred Lectures at Johns Hopkins University, the Author Gives Some Valuable Hints on Choosing Engineering Equipment

By A. S. LOISEAUX

IN THE purchase and erection of engineering equipment certain well-defined steps are generally necessary, which may be outlined as follows: Determination of work to be done by the equipment; choice of general character of equipment to do the required work; specifications to cover construction and performance of the various parts of the structure and equipment; contracts to cover price, terms of payment, time and point of delivery, erection and initial operation; following up manufacture, delivery and erection, inspection of material and equipment, and necessary testing to ensure that all terms of contract are fulfilled.

The engineer's object in choosing methods and equipment to accomplish desired results should be to get maximum reliability and efficiency with an ultimate minimum cost for fixed charges and operation. This object can generally be achieved by the employment of the best equipment obtainable, of ample capacity, and simple and rugged construction. This kind of installation will not be the cheapest to buy or install, but will figure the cheapest in total cost over a period of years of operation. The engineer should realize that the final judgment of his work is not a theoretical or technical matter. His work will be judged by the same hard, practical tests that all other work is judged by. Does it work? Does it pay? Does it stand the test of time?

To illustrate in a practical way the steps mentioned in the purchase and erection of engineering equipment, we will take the problem of unloading coal from barges at a water-front and transferring this coal to the bunkers of a boiler-house about 300ft. distant from the water-front and 70ft. above the water.

Determination of Work to be Done by the Equipment.—The engineer's first step is the determination of the work to be done by the equipment.

The power-plant design in the case which we have taken as an example contemplated an ultimate development calling for a maximum power-house output of about 120,000 kw. If 2.5 lb. of coal is burned per kilowatt-hour, this output would require a maximum use of coal of 300,000 lb. per hour, or 150 short tons per hour. A load factor of 80% would indicate a maximum requirement of 2,880 tons per 24-hour day. It is, of course, desirable to unload coal in daylight in a working day of eight hours, making the capacity of coaling equipment large enough to supply maximum ultimate coal in an eight-hour working day. This condition to supply 2,880 tons per day of eight hours would require an outfit of 360 tons capacity per hour.

It is evident that there is much latitude allowed to the judgment of the engineer in the determination of the first point—that is, the capacity that he shall require of the equipment. One device working eight hours for maximum coaling must be 360 tons per hour capacity, an equipment working twelve hours would be 240 tons capacity, and an equipment working twenty-four hours would be 120 tons capacity.

It must also be remembered that it is not good engineering practice to rely on one equipment of this character for the entire supply of a station. The final judgment as to the best capacity applied to this problem was to provide two duplicate coaling equipments, only one to be installed at first, each equipment to have a maximum capacity of 300 tons per hour, or be able to supply maximum coal requirements in a ten-hour working day. This gives reliability even under break-down conditions, as each tower can supply the plant with coal.

In choosing permanent coaling equipment for the new house, the gantry type was eliminated because of its slow operation. The low-type unloader with cars and skip hoist was eliminated because of its complication.

A low-type unloader with inclined conveyer and belt distribution over bunkers was proposed by a firm manufacturing coal-handling machinery, but it was rejected because of the multiplicity of parts. The equipment finally determined on was a high-speed coaling tower located on the water-front, with a structural-steel boom overhanging the water. A bucket grabs coal from the barges and lifts it into a receiving hopper 105 ft. above the water.

FIG. 3—HIGH PRESSURE CYLINDER AFTER WELDING.

From this hopper the coal passes through a two-roll crusher and into another hopper directly above a cable railroad. The cable railroad is on the level at the top of the coal bunkers in the boiler-house to be served. The cars are circulated in an endless route from the coaling tower over a bridge to the boiler-house, their load of coal is dumped in the proper bunkers without stopping, and the cars return to the coaling tower to be loaded.

This equipment is perhaps as simple as possible. All the elevating is done in one lift when the coal is picked up from the barge. Gravity then causes the coal to flow through hoppers and crushers to the cars. Horizontal transportation is done entirely by cars which are most reliable and efficient for that purpose.

An inspection trip was made by the engineer in charge of the coaling problem to view the actual performance of similar towers, both steam-driven and electric-driven, to determine what were the valuable and undesirable features of each. It should be here remarked that it is most important for an engineer actually to see the operation of equipment similar to what he expects to purchase, because some important features will at once appeal to the eye which may be overlooked in a specification or description. It is also desir-

able to question men in charge of actual operation, as they sometimes give information not available from other sources.

Specifications to Cover Construction and Performance.—Having chosen the general character of coaling apparatus, it is necessary to specify the construction and performance required of its several important component parts.

No engineering student should imagine that an engineer can sit down and evolve complete specifications for highly developed equipment. This method has been sometimes attempted, probably more in European than in American practice, and the results cannot well avoid being inferior. The proper method, and one almost universally followed, is to call upon manufacturing and constructing concerns for their proposed specifications for equipment and construction to accomplish the desired purpose.

To obtain best results it is, of course, necessary to invite the most reliable and capable firms to bid. If the engineer is in doubt who is best fitted to do certain work or supply certain equipment, he can get such information from several convenient sources.

The advertisements of technical and trade journals are constantly revised lists of bidders. The engineering-society journals carry announcements and advertisements of capable firms. Directories sometimes give a full list of manufacturers and outline their products. From these and other sources of information the engineer can quickly get, if he does not already know, the names of proper parties to confer with on the prospective work.

For competition it is, of course, necessary to have two or more bidders. It may be advisable to have as many as five if there are that many entirely competent parties. Beware, however, of inviting the irresponsible or incapable bidder. He will make promises he cannot fulfil, or quote a low price that will not see him through the contract, and then abandon the work. The character of a contractor is important. One will haggle at every doubtful point and seek extras at every turn. Another will fulfil his contract without question and give his client the benefit of the doubt.

A good rule in the selection of bidders is to invite only those whom you are willing to have do the work, and treat them all impartially, awarding the contract to the one offering the best proposition, all things considered, which does not always mean the proposition of lowest price.

Caisson Foundations.—In the case of the coaling tower under consideration the two most experienced foundation concerns in the country were turned to, with the result that one company built the caissons for the first tower, and the other company the caissons for the second. By turning to the engineering and construction firms best fitted in the States for this work, we have not only secured permanent structures, but were ourselves relieved from the serious responsibility of providing foundations that might fail under adverse conditions.

Structural-steel Tower and Bridge.—The steel structure for tower and bridge was roughly designed by the owner's designers—that is, the general size and character of the structure was determined, and loading given. The result is called a setting plan. This drawing or setting plan was then submitted to the structural-steel firms for competitive bids, it being specified that the successful bidder should completely check the design and be responsible for its strength and detail in all of the parts. The price in such cases is given on a tonnage basis, so that moderate changes in design or size of members will not affect the contract.

A personal conference with capable engineers of a manufacturer will accomplish more than weeks of corresponding. It is also highly desirable to have the contracting engineer familiar with conditions on the site.

Engineers or manufacturers are ready and anxious to explain the design and merits of their apparatus, and by giving each bidder an attentive hearing the purchasing engineer can gain valuable knowledge of the apparatus offered with minimum expenditure of time and effort.

The engineer in charge should remember to inquire for possible improvements beyond what the manufacturer's specifications may contain.

In drawing up specifications for automatic equipment it should be remembered that labour is, in general, the most expensive item in operation, and where it is possible to eliminate a single labourer at a wage of 3.50 dols. per day, or, say, 1,000 dols. per year, an investment as high as 5,000 dols., or even 10,000 dols., may be justified. Interest and depreciation on the investment should pay the labourer's wage, and operation will in general be more reliable and rapid than with the labourer. It will often be found that the value of more rapid operation is greater than the saving in operating wages.

Contracts to Cover Price, Terms of Payment, Time, Etc.—After specifications have been evolved, it is necessary to enter into contracts for the different parts of the work to cover price, terms of payment, place and time of delivery, provision for erection, initial operation, and tests of equipment.

Contract form are nearly always provided by manufacturers with clauses protecting them from numerous possible contingencies. The owner's engineer should scan these carefully and eliminate or modify any that may be unsatisfactory or unfair.

A valuable method to compare all important competitive bids is that of tabulation. In tabulating bids parallel columns are provided, headed by different makes of apparatus available. The character of apparatus, with all its important features, method of control, operating characteristics, capacities, speeds, sizes, weights, materials, etc., is tabulated in these parallel columns This method of analysis enables differences to be quickly and accurately located. It discloses which is the best proposal, and enables the best to be improved by requiring changes in the specifications submitted to provide for any superior features that may appear in any of the other specifications. By this means of comparison and selection remarkable results are sometimes obtained in procuring apparatus of high reliability and general efficiency.

Price and Terms of Payment.—Price is a matter of competition with due regard to difference in material and equipment furnished. It is well to have inquiries for prices contain the statement that the owner reserves the right to reject any or all bids submitted. The experience and reputation of the contracting firm must be considered, and price difference allowed in favour of a concern of ample responsibility to meet emergencies that may arise or bear losses that may occur. In terms of payment it is customary to allow 40 or 50 per cent. on submission of bills of lading proving shipment. Contractors will usually call for two additional payments, one at 30 days and one at 60 days after shipment. These terms are in general not satifactory to the owner except in the case of standard equipment. It is necessary for the protection of the owner's interest, when equipment is at all special, to provide a final payment of 25 per cent. or more after complete erection and satisfactory operation of the apparatus. This safeguards the owner from carelessness on the manufacturer's or contractor's part in not putting equipment in final and satisfactory operating shape, and provides the owner with a whip to require the full performance of the terms of the specifications and contract.

Point of delivery should be carefully specified, as many troublesome delays are due to lack of full information as to this matter.

Erection is best placed with the same concern that provides structure or equipment as before noted. If for good reasons it must be given to separate concerns, it is necessary carefully to specify how and where the material is to be delivered, who shall unload and move it to the permanent site. It is necessary to state what responsibility shall be taken by the erector and what by the manufacturer or owner. Insurance is generally necessary to cover accident during erection, and it should be stated that defects of erection shall be made good without loss to the owner.

It is necessary to specify conditions governing overtime in erection. These additional expenses can be placed on the

manufacturer if delivery is late, but only when so specified.

Extra work must be mentioned, giving the terms and rates at which such work shall be done.

Actual operation is the final test of all equipment, and considerable periods of time should elapse whenever possible before final payments are made, as it is possible for radical defects to develop after a short period of successful operation. The owner's engineer must be careful not to commit himself in word or writing as to his final acceptance of equipment until it has been in full capacity operation for a considerable period.

Contracts on Basis of Cost.—There are some situations when it is desirable to enter into a contract on the basis of the cost of the work to the contractor. Such a situation exists when the cost is doubtful, by reason of unknown conditions of soil for foundations, unknown conditions of stream flow or weather, or the like, which may greatly influence the cost. The risk in such cases belongs to the owner, not to the contractor. The contractor could not take this risk unless he included a high figure for contingencies in his bid, or gambled on his chances of good luck in construction. A contract based on cost must define cost carefully, stating particularly what percentage is to be charged for overhead costs, or whether overhead is to be included in a percentage to cover profit as well.

In contracts for field work the cost of "plant" must be explicitly stated. It is generally to the owner's interest to agree on a flat sum to cover all plant rental, specifying, however, the main items of plant that may be required. This makes it to the contractor's interest to finish the job promptly, to use his plant elsewhere.

After paying all costs, including overhead, it is common to allow the contractor a net profit of 5, 10, or 15 per cent., depending on the conditions and the magnitude of the work. Another method, however, which has an important advantage, is to give the contractor a fixed fee for his services over and above his costs, including overhead. This also tends to expedite the work, as the contractor cannot increase his fee by delays or increased costs.

Following Up Manufacture, Delivery, and Erection.—After contracts have been signed embodying all specifications, it might be supposed by the engineering student that the engineer's work was finished, but such is far from the practical fact. To obtain what we have specified at the right time usually requires a large amount of effort in following up the various manufacturers and construction men.

In all important equipment where time has a large financial value, it is wise and often necessary to have a follow-up system, keeping track of the progress and manufacture, especially of the heavier parts such as large forgings and castings to ensure that delivery will not be greatly delayed. It is the customer who follows his work the closest and inquires most persistently and explicitly of the manufacturer that gets the best service from the factory. A trip to the factory to see the exact status is often necessary and profitable.

An effective means of securing results in deliveries and erection is the formation of a tabulated schedule specifying all the important parts of a completed job at the side of the tabulation and making spaces showing time intervals at the top of the tabulation. The desired progress of the work can then be chartered from the beginning of manufacture or field work to the completion of the job.

The foreman in charge of erection decidedly influences the speed and quality of the work. When an unusually capable foreman is known, his services may be called for by the owner with good results. A foreman should have support in getting labour and material, and in some cases where time is valuable, he may be given a bonus for completion earlier than the normal time for erection.

Completion is often specified in number of working days rather than by definite date. This is justified for outdoor construction, especially in winter, when the contractor is prevented by the weather from making progress on certain days.

Operation of Equipment—Operation is not only a test of whether specifications have been met, but is also a gauge of the engineer's success in obtaining desirable features that are not or cannot be included in specifications. For instance, such qualities as quietness of operation, freedom from vibration, rigidity of structure, convenience and ease of control, are not generally subject to specifications in any exact terms, yet they indicate the degree of skill with which the design has been made and carried out.

In companies having a purchasing department the engineer works through such department in most of his official acts, such as the invitation to bid or the awarding of a contract. Engineering interviews are a part of the engineer's duties to arrive at correct decisions, the final results of his work in the form of specifications and orders or contracts being sent through the purchasing department and company's officials to maintain uniform records and secure proper approval of important purchases.

The purchase of electrical machines has been simplified by the issue, some years ago, of the standardization rules of the American Institute of Electrical Engineers. These rules specify standard temperatures, ratings and methods of testing for electrical machines, to which most manufacturers now conform, so that their guarantees are generally directly comparable.

A successful engineer is one who applies common-sense to every step of his work, devising means to get results desired by the simplest and most direct methods. The engineer's educated judgment will enable him to choose the best design and equipment of various alternatives submitted, but he needs great diligence and determination to drive an undertaking through from its inception to a successful and timely completion.

THIS MAN KNOWS THE VALUE

The engineer of a well-known municipal electric light plant in Ontario writes "Power House," as follows:

> "New subscribers who do not really know the value of POWER HOUSE might demur at paying a high price for it, but personally speaking, I would not object to paying double price for double service. **I never miss reading the advertisements. They are real interesting to anyone in this line."**

Anyone associated in any way with power development or combustion should read "Power House" ads. and editorial. The apprentice will find the paper one of great educational value. Hundreds of engineers and others in good positions to-day thank "Power House" for the effective way it has assisted them.

BOOKS RECEIVED

We have received a "Data Book for Engineers" compiled and published by the Locomotive Superheater Company of New York. The book has been prepared with a view to the requirements of the stationary engineer in his every day duty, and it certainly fulfils its aims. The first few pages are devoted to a discussion of superheated steam, after which follow the various tables. These are very complete and cover a wide field, two very useful ones being those dealing with fan sizes and speeds, for various quantities and pressures of air in ashpits. A series of tables giving dimensions of various types of boilers should be of great use to those engaged in installation work, or considering additional installations in an old building. Drill sizes, sizes of standard pipes, boiler tubes, etc., will be found here, and others of practical use to the engineer. The book is strongly bound and will be forwarded on request by the Locomotive Superheater Co. to anyone who is interested in steam engineering.

TRADE ANNOUNCEMENTS

F. H. Imra and partners, civil and mechanical engineers, Hope Chambers, Ottawa, have been appointed agents for the Power Plant Company, Ltd., of West Drayton, England. The company, who are specialists in gear cutting, produced the first turbine reduction gears made, and have achieved a great reputation in this line. They also manufacture flexible couplings, brakes, gear cutting machinery and tools.

The Theory and Practice of Electricity

In These Articles the Theory Will be Developed Sufficiently to Enable the Practical Man to Grasp the Underlying Principles of Apparatus Under His Care, Both Direct Current and Alternating

By W. F. SUTHERLAND

IN THE last lesson the relation between electricity and magnetism was discussed and it was shown that every conductor carrying a current of electricity was surrounded by a circular magnetic field and that it was quite easily possible to make use of this circular magnetic field in the construction of an electro-magnet. In this section, this relationship will be further developed, this time from the magnetic side and the action of a magnetic field of force on a conductor.

It should be noticed that we say field of force and the distinction between force and work in this connection should be clearly understood. A permanent magnet exerts force on other magnetic bodies in its neighborhood, but does no work on them unless they be free to move. If they are, and are drawn towards the magnet, then the magnet does work on them, changing their position against the forces of friction, springs or what not. It is as if a weight had been on a table and had fallen off, to the floor, being attracted downwards by gravitational force.

If the piece of iron were now pulled away from the magnet to its former position work would be done upon it and energy stored up in it by virtue of its changed position.

Failure to distinguish between force and work has caused many a misguided inventor to chase that elusive will of the wisp—perpetual motion, and this is true in the electrical field as in other and older branches of science.

If we were to take a permanent magnet and holding it over a piece of steel, fastened in place, by moving the magnet up and down, we would find that while quite easy to approach the steel it would be harder to draw it away and in doing so we would be doing work. Something similar happens when a bar magnet is thrust into or withdrawn from a coil of wire of which the ends have been connected together; only, in this case it will be found that the magnet is just as hard to push into the coil as it is to withdraw. If the ends of the coil are left unconnected the presence of the coil of wire has no effect upon the ease of movement of the magnet. Here is an effect which one might surmise to be caused by a flow of electricity in the coil of wire, work being expended in causing the flow. This is the case and if the heads from the coil were connected to a sensitive voltmeter a kick would be observed every time the magnet was thrust into or withdrawn from the coil. When the magnet is held stationary in any position the current will cease to flow, the mere presence of it having no effect if movement is absent.

When the bar magnet is suddenly plunged into the coil the voltmeter shows a decided deflection, coming back to the zero point as the bar magnet comes to rest, and when the bar magnet is withdrawn, while a similar effect is observed, the needle of the voltmeter swings in the opposite direction.

One can reason out for himself that a changing magnetic field of force or a cutting of the lines of force by a wire creates a tendency for current to flow and if the wire be joined upon itself as in a coil with the ends connected the current will actually flow while the magnet is moving, the work necessary to move the magnet being expended in the form of heat in the wire through which the current passes. The effect of changing magnetic strength is also shown in Fig. 29, which shows two coils of wire wound around a common iron core. One of these coils is connected to a few dry cells or other source of current, with a switch in circuit for closing or opening it. The other coil is connected up to a galvanometer or volt meter. On closing the battery circuit the voltmeter needle will swing in a certain direction, quickly coming back to zero, and on opening the circuit by means of the switch the needle will be deflected in the opposite direction, again swinging quickly back to zero. This is the principle underlying the

FIG. 28.

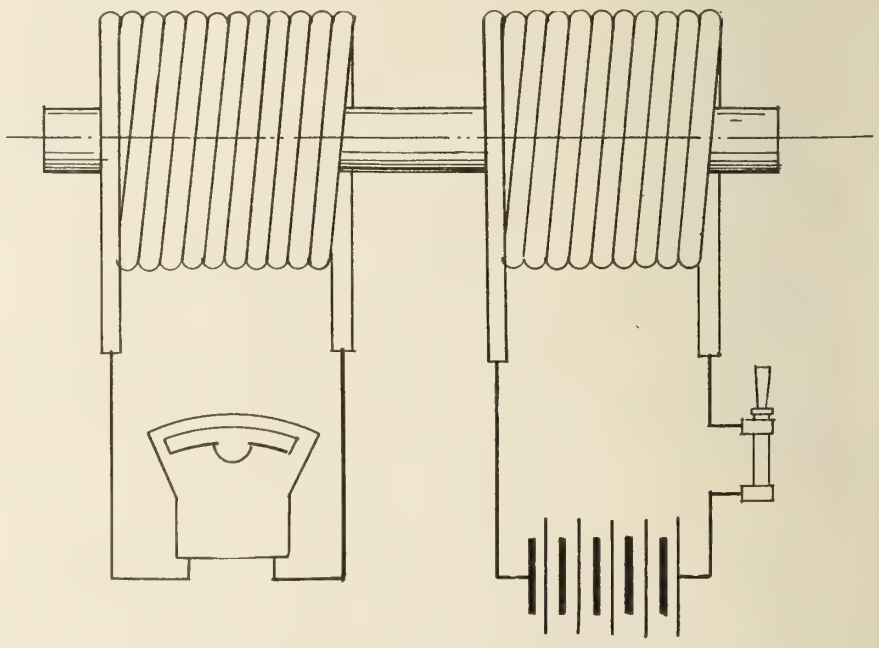

FIG. 29.

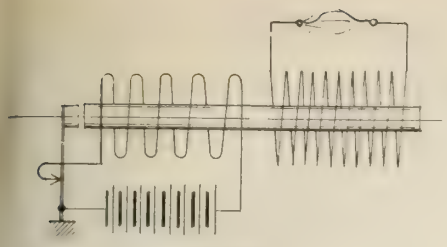

FIG. 30.

familiar induction coil or spark coil of the gasoline engine. An elementary diagram of the same is shown in Fig. 30. Some of the accessory equipment has been omitted for the sake of clearness, notably the condensor. The battery shown is connected to the primary of the coil through a vibrator consisting of a spring with a piece of soft iron

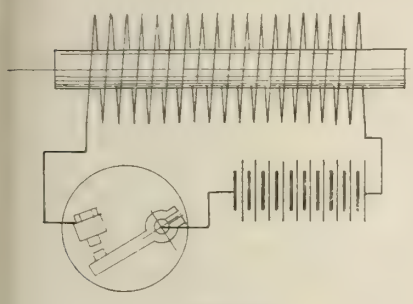

FIG. 31.

attached to the free end. One lead is connected in solid to the vibrator, while the other is attached to a point which just touches the spring in when it is at rest. When a current is sent through the primary the iron core is magnetized and draws the vibrator spring towards itself. In doing so it breaks the primary circuit and this cycle is repeated indefinitely. Each time the primary circuit is made complete the magnetic flux in the coil builds up and at each interruption it dies down. As it builds up a current is induced in the secondary winding and as the flux dies down another current is induced but in the opposite direction. The further operation of apparatus of this type will be better understood when the study of alternating current is taken up.

We need not use two separate coils, but as in the familiar make and break ignition system one cell only can be wound on the iron core. A diagram of a make and break system is shown in Fig. 31. The coil consists of a large number of turns of fairly heavy wire wound upon an iron core and connected up with contact points in the engine itself. When these are closed the current flowing builds up the magnetic flux in the iron core and when the points separate the flux dies down. In dying down an electro-motive force is generated in the many turns of wire which causes a fat spark to jump the points as they separate.

In all the above the induced electro-motive force is produced by an increase or decrease in strength of the magnetic field. In other words the lines of force linking through the coil of wire have been changing in number. It is not necessary that the magnetic flux or the number of lines of force change, exactly the same result can be secured by moving a wire across a magnetic field of uniform strength.

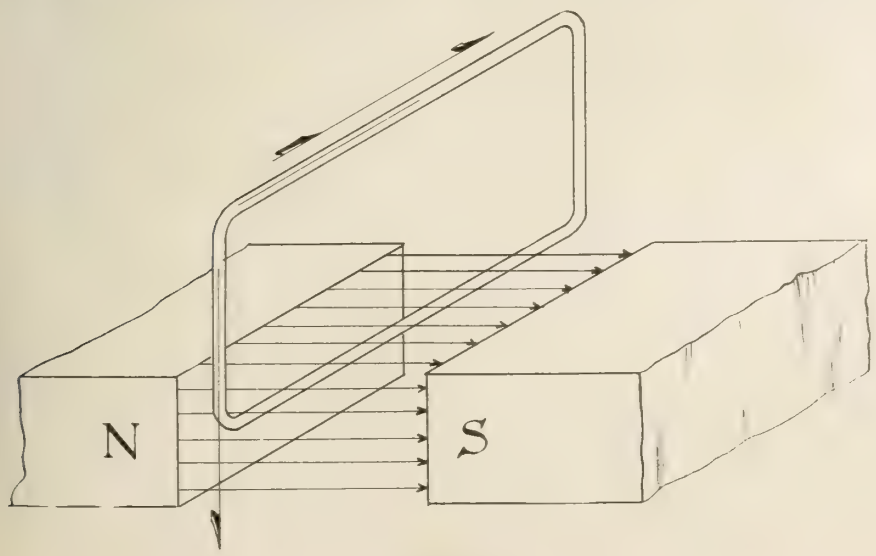

FIG. 33.

When a conductor is moved in a magnetic field in such a manner that it cuts the magnetic lines of force, an electro-motive force is generated in the conductor which tends to cause a flow of current. The magnet is not weakened by the generation of an e.m.f. in a conductor and the consequent flow of current, but the energy necessary for this is derived from the work necessarily exerted in moving the conductor through the magnetic field.

In Fig. 32 are seen the north and south poles of two magnets, with a wire between them. The magnetic flux is shown traveling between the two pole faces from north to south as indicated

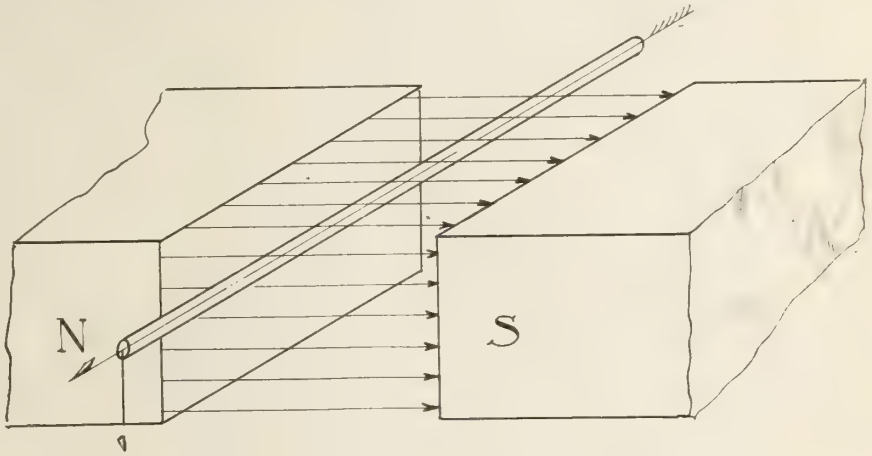

FIG. 32.

by the arrows. If a wire be forced downward between the two poles as shown an electro-motive force will be generated in it which will tend to cause current to flow towards the observer, as shown by the arrow pointing through the wire.

Fig. 33 shows a closed loop of wire being forced through a similar air gap between magnets and in this case it can be said that the e.m.f. is generated by a variation in the number of lines of force linking through the coil.

A MATHEMATICAL CURIOSITY

If you were told that 4 was equal to 5 you would immediately conclude your informant had escaped from a home for the feeble minded. Yet it can be proved. Here it is:

$$16-36=25-45$$

$$16-36+\frac{81}{4}=25-45+\frac{81}{4}$$

$$\left(4-\frac{9}{2}\right)^2=\left(5-\frac{9}{2}\right)^2$$

$$4-\frac{9}{2}=5-\frac{9}{2}$$

$$4=5$$

Authorization has been received by The Ontario Steel Products Co., Ltd., to increase their capital stock from $1,500,000 to $2.750,000, the increase to consist of 12,500 shares of $100 each.

Report of the Committee on Prime Movers

The National Electric Light Association Committee Presented This Report on Hydraulic and Steam Prime Movers at the Forty-Third Annual Convention of the Association.

THE important feature of the past year's development is the increased size of water wheels installed. The growth of operating systems makes feasible this increased size, individual units of approximately 40,000 h.p. capacity having been installed and larger ones being contemplated. One large manufacturing company reports the starting of a total of nearly one-quarter of a million kilowatts in large hydro-electric generators in units of over 12,000 kw. each. In addition there are a large number of smaller vertical direct-connected wheels being installed as additional or replacement units.

Progress and Development of Hydraulic Prime Movers

The tests of the large water wheels in place show remarkably high efficiency, which makes it profitable in a great number of cases to replace old installations with new. The new large units are uniformly distributed over the United States. Many of the older hydraulic developments which used dams and canals, supplying widely scattered individual water wheels, are now planning a single hydro-electric station to utilize the entire fall and transmit the power electrically.

Several large units have been started and continuously operated for over a year without a single shutdown on account of wheel troubles.

A new type of water wheel for low-head plants using an exceptionally high-speed runner has been developed by Forrest Nagler of the Allis-Chalmers Company.

Four 15,000-h.p. tangential wheels for operating under an effective head of 1,008 ft. have been ordered by the Great Western Power Company. These wheels contain 21 buckets, each 36 in. wide and 24 in. deep, and water is supplied from 13 nozzles. They are to operate one each overhung from the ends of a 22,000-kva. generator shaft running at a speed of 171.4 r.p.m. It may be of interest to state that several water-wheel manufacturers designed and recommended Francis-type wheels for this head at a speed of either 600 r.p.m. or 750 r.p.m. The operating engineers, however, were afraid that the erosion on the clearance passages and gate mechanism might be rather severe when operating under a pressure of over 430 lb. per sq. in. This, coupled with the fact that it would require a turbine-type generator with smooth-core field which was not suited for charging conditions on their long-transmission line, led them to choose the impulse wheel.

There are at present under construction some 800-ft. Francis wheels for the Southern California Edison Company, to be run 600 r.p.m. and deliver a maximum horsepower of 22,500.

Automatic hydro-electric plants are receiving considerable attention. These plants operate without attendants, and the gate openings and output are regulated according to the water supply available, by means of a float control from pond level. These plants may be tied into a local power system or be run in connection with a stream station which takes care of the fluctuation of load and varying flow of stream.

There is a radical tendency, where climatic conditions are favorable, to confine the power station building to the housing of control apparatus only, locating generating apparatus step-up transformers and high-tension equipment outdoors.

General practice is divided between the centralization of auxiliaries and a tendency to make each large unit self-contained with its own exciter, governor, pumps, etc. A satisfactory solution of this problem is accomplished by having individual speed-control sets for each of the main units and by having an emergency pipe connection from each individual set to each adjacent set. Each main oil-pressure set is of sufficient size to operate two main units under emergency conditions. Thus all of the advantages of the central oil-pressure system are combined with the advantage of the individual system.

Hydraulic Operation and Combined Operation of Hydraulic and Steam Plants

The combined operation of hydro-electric and steam-electric generating stations has become a subject of vital interest to the central-station industry. It will be increasingly important in the future, since the marked trend toward interconnection will bring more and more steam plants into paralled operation with hydraulic plants, and will make possible the development of water powers which cannot now be utilized economically. Yet intensive study of the subject is comparatively new. Individual companies and systems have made more or less careful analyses of their own conditions and problems, but there has been little information exchanged or published. During the past year the committee has considered or has had brought to its attention a large number of problems. These are listed below with the idea of having before the committee an outline to be followed in future work.

The problems of combined operation and hydraulic operation may be classified under the three heads outlined below: namely, (1) problems of the combined system; (2) problems of the steam plant; (3) problems of the hydraulic plant. Some problems of purely hydraulic operation are included in the third group, although they do not depend on combined operation.

I—Problems of the Combined System

A—Parallel operation of co-operative systems:

1. Contract relations between hydraulic and steam plants.
2. Advantages and disadvantages of interconnection.
3. Division of load between hydraulic and steam plants.
   (a) High-flow operation.
   (b) Low-flow operation.
4. Division of wattless current between hydraulic and steam plants.
5. Frequency regulation and governing.
6. Relative reliability of hydro-electric and steam-electric service.

B—Parallel operation of non-co-operative systems:

In this group there are other problems which are chiefly electrical and do not fall within the scope of the prime movers committee, but it should be mentioned that a complete study of combined operation would include the following problems: Increased damage to property and interruption to service which may result from greater capacity feeding in so short-circuits; protective methods; the use of reactance to limit short-circuit currents; the effects of such reactance on voltage and synchonizing power; voltage regulation; synchronizing power of tie lines.

II—Problems of the Steam Plant

1. Standby service.
2. Minimum load on steam turbines.
3. Time required to start up steam turbines.
4. Shutting down steam plant during "off-peak" hours.
5. Banking practice as related to combined operation.
6. Novelties and difficulties in operating.
7. Station design as affected by combined operation.

III—Problems of the Hydraulic Plant

1. Efficiency measures to secure maximum output or water economy.
2. Measurement of water.
3. Dispatching of water and hydrographic methods.
   (a) When the water is used by one plant.
   (b) When the same water is used by two or more plants.
4. Ice troubles and methods of fighting same.
5. Power requirements and operation of auxiliaries.
6. Planning of maintenance, inspection, and repairs.

7. Operating rules and procedure.
8. Novelties and troubles in operating.
9. Station design as affected by combined operation.

From this analysis of the problems of the combined operation the report considers the points in detail, outlining the information required for further reports and giving some data that have been discovered in the solution of the subdivisions of the problems. The report states that every system must constitute a separate problem, but it is believed that many principles and conclusions will have a common application to a large number of systems. In abstracting the remainder of the report, material will be included where new information has been submitted.

I—Problems of the Combined System

A—Parallel operation of co-operative systems

1. Contract Relations Between Hydraulic and Steam Plants.—The ideal in every combined system should be minimum over all cost of delivery to the ultimate consumers. The solution of the problem, where hydraulic and steam stations are separately owned, lies in some sort of flexible arrangement on a co-operative or cost and profit-sharing basis in which rigid limits of power and energy are disregarded and the maximum output of the hydraulic plant is utilized as far as possible. Such a solution furthers the conservation of our natural resources in which the central-station industry is vitally interested.

3. Division of Load Between Hydraulic and Steam Plants.—Under this head the report calls attention to some instances where steam generation is necessary in spite of the fact that the hydraulic plant is carrying the load. Such steam generation may be necessary for maintenance, economy or safety of steam-plant equipment, or reliability of service. Unnecessary steam generation may be caused by faulty governing or load dispatching. Under a discussion on the unnecessary steam generation due to faulty governing or load dispatching, the report points out the necessity for a graphic meter giving total station output for each generator station, and the necessity of means of communicating output figures from all generating stations to one central point.

The importance of not having the hydraulic capacity of the turbine limited by the generator capacity is also emphasized.

4. Division of Wattless Current Between Hydraulic and Steam Plants.—In the case of a hydraulic plant operating in parallel with the steam plant, the problem consists of comparing aggregate steam costs for high load factor but increased steam generation due to hydro losses, with steam costs for a poor load factor but a smaller amount of energy output. If the hydro plant has large storage or high head and little tailrace backwater, so that the reduction in head due to low load factor is not great, it will usually be found that it is most economical for the hydro plant to take the poor load factor. The result may be reversed if the percentage loss of delivered output from the hydro plant is considerable and if the percentage increase of steam costs due to lower load factor and variations is negligible.

6. Relative Reliability of Hydro-electric and Steam-Electric Service. The report is quite positive in its statement that in recent years particularly the individual hydraulic prime mover is more reliable than the individual steam turbine. The present-day single-runner vertical-type water-wheel-driven generator equipped with a Kingsbury bearing seems to give almost perfect continuity of service. It has been nearly always found that hydro service can be restored before the steam plant can pick up a large proportion of the load even with a number of boilers held ready under "hot bank." As a result, with modern conservative construction of transmission lines, there is very little pure stand-by service in the East and Middle West. On the Pacific coast, where use of fuel oil makes quick firing possible and transmissions of great length with considerable inherent voltage drop, extensive stand-by service is more common.

II—Problems of the Steam Plant

1. Stand-by Service.—It is stated that in coal-burning plants underfeed stokers with forced draft and fan and ram speed control, or chain grates with forced draft may be found most satisfactory for quick starting. Future developments will be along the line of using oil and coal under the same boiler, and of adapting pulverized fuel for large central station use.

The example of the municipal plant of Zurich, Switzerland, is cited as demonstrating that during off-peak hours stand-by boiler pressure may be supplied electrically from the hydro-electric plant. In this case, the use of electricity for which there was no market was more economical than paying for banking coal.

2. Minimum Load on Steam Turbines.—Motoring, even with a certain amount of steam entering the turbine, dropping below a certain minimum turbine load, and sharp fluctuations of load are regarded as injurious to large high-speed steam turbines by many operating engineers in eastern plants.

On the Pacific coast, however, the steam turbines have been floated on the line with practically no load, and in some cases, as synchronous condensers, with less than no load steam entering the turbine without apparent damage.

4. Shutting Down Steam Plant During "Off-Peak" Hours.—To avoid the difficulties caused by accumulation of water in pipe lines and leaky joints, occurring in the steam plant during shut-downs, some plants operate at least one boiler at near normal rating during the off-peak hours and use the steam thus generated to operate a small unit, circulating the steam through all the steam mains before it reaches the unit. In other cases the generating plant is shut down entirely, but steam is blown off for some time near the turbine inlet before the unit is started up.

5. Banking Practice as Related to Combined Operation. A steam plant carrying the peak loads of a combined system operates at a poor load factor and therefore has an increased amount of banking. The report gives the result of a 42-hour banking test on a 822-h.p. Stirling boiler with underfeed stokers as 0.112 lb. of 13,500 B.t.u.. coal per rated boiler h.p. banking hour. The pressure being allowed to drop about 15 lb. below normal, coal was added after 16¾, 28¾ and 40 hours. The steam generated after the bank had nominally begun was approximately measured and an equivalent amount of coal deducted. In a similar test on oil-burning boilers a value of 0.046 lb. of oil per h.p.-hour was found. This is equivalent in heating value to 0.063 lb. of 13,500 B.t.u. coal.

6. Novelties and Difficulties in Operating. The percentage changes in load on steam plant are very greatly increased when the hydro plant takes flat load during high flow. This condition makes a foreknowledge of load variations essential to avoid excessive blowing off through safety valves or reduction of hydraulic output. To assist in estimating load in the boiler room, the Ashley Street Station of the Union Electric Light and Power Company of St. Louis operating in parallel with the Mississippi River Power Company and equipped with a number of varying sizes and types of generating units of which a kilowatt load does not give an accurate idea of the boiler room, has adopted a novel unit called the "kilber." The kilber is 1,000 lb. of steam per hour. The boiler room is regulated by the number of kilbers required, an estimate of which is furnished from the switchboard at half-hour intervals.

III—Problems of the Hydraulic Plant

1. Efficiency Measures to Secure Maximum Output or Water Economy.—The report contains a detailed consideration of the operation of the Holtwood Station for information under the above heading. This station operates most of the time in parallel with one, frequently two, and rarely with three, steam-generating stations. Energy is transmitted at 70,000 volts to Baltimore, Md., 40 miles distant, and to Lancaster, Pa., 15 miles distant.

The Holtwood Station is on the Susquehanna River, the flow of which varies from about 3,000 to about 700,000 cu. ft. per sec. The average height of the dam is about 55 ft. and flashboards of a height of 2½ ft. or 4½ ft., according to the season, are usually installed on the crest. Except during high floods and extreme low flow, the working head varies from about 47 ft. to 62 ft. The area of the pond at the elevation of the dam crest is less than four square miles. There are eight main turbines of the vertical shaft, inward and downward flow Francis type. The total of the turbine ratings is 118,000 h.p. (ratings are not, however, at the same head). (Report of committee on prime movers, presented at 43rd convention of the National Electric Light Association, May 18-22, 1920, pp. 105-128.)

A Course of Instruction for the Graded Certificate

We Will in This Course Go Through the Mathematical and Theoretical Work to Cover Every Grade of Certificate Issued by the Ontario Board

By T. H. FENNER

WE considered in the last article the various forms of lap joints, and now come in logical sequence to the butt strap type. These are double riveted, triple riveted, and quadruple riveted, the triple riveted being most in use. They are called butt strap joints because the edges of the plates to be joined are butted together and are secured by straps or plates of metal, which cover the joint, inside and outside, and are riveted through straps and plate to make a solid joint. This type of joint makes for a high percentage of strength, and at the same time preserves the truly cylindrical shape of the boiler. The rivets, being in both double and single shear, thereby gain in strength. A rivet is said to be in double shear when it holds together three plates, and therefore before it can be sheared has to be cut through in two places instead of one. The shearing strength of such a rivet is usually allowed to be 1¾ times the shearing strength of a rivet in single shear.

In the double riveted double strap butt joints the straps are usually made equal in width on the inside and outside of the joint and the full number of rivets is used in each row. In the treble riveted double strap butt joint the outside strap is only made wide enough to take in the two inside rows, and every alternate rivet is left out of the outside row. In the quadruple riveted double strap butt joint the straps are also unequal, and besides every alternate rivet being left out of the third row, two rivets are left out of the outside row. In some cases the strap is cut away on the outside edge to conform to the rivet line of the third row, thus securing a better caulking edge. This is not universal practice, but is a feature of some well-designed joints. The writer knows of at least one joint of this type with an efficiency of 92½ per cent.

When designing a joint of the butt strap variety, the same procedure is gone through as in the others. We have also to consider the thickness of the straps, and the Ontario regulations give a definite rule for determining this dimension. The thickness of straps where the full number of rivets in each row is used and double straps is found from the formula

$$T_1 = \frac{5}{8} T$$

where T_1 is the thickness of strap and T thickness of shell plate. For double straps when straps are unequal in width and every alternate rivet omitted in outer row

$$T \frac{5T \times (P - d)}{8 \times (P - 2d)}$$

Suppose we consider first a double strap double riveted joint, with equal straps and full number of rivets in each row. In a joint of this kind all rivets are in double shear, and therefore we must reckon for the number of rivets in a pitch $2 \times 1.75 = 3\frac{1}{2}$. This will of course have the effect of increasing the rivet strength, and in order to equalize it we must increase the pitch, which brings up the plate strength.

Suppose we wish for a plate strength of about 80 per cent., let us see what results we can obtain. We have $\frac{p - d}{p} \times 100 = 80$, and if we assume a ⅜-inch plate and ¾-inch diameter rivet we get

$$\frac{p - d}{p} \times 100 = 80$$

$$p - d = .8p$$

$$d = .p - .8p = .2p$$

Then if d = .75, the pitch will be

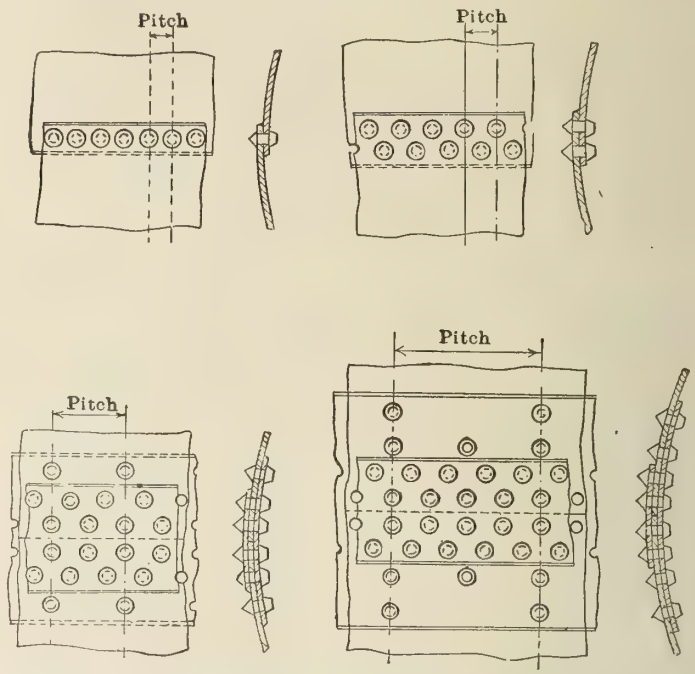
$$\frac{.75}{.2} = 3.75$$

With a pitch of 3.75 inches, diameter .75, and plate strength efficiency of 80 per cent., what will be the rivet strength efficiency? Let us work it out, taking C as .7:

$$\frac{a \times n \times c}{p \times t} - \%$$

$$\frac{3 \times 3 \times .7854 \times 7 \times 4 \times 8 \times 70}{4 \times 4 \times 2 \times 15 \times 3 \times 100} = 76.9$$

say 77 per cent. which is within 3 per cent. of the plate strength, and may be taken as a pretty evenly balanced joint. We could increase the strength of the rivet section by decreasing the pitch, but this would also decrease the plate strength, and as we have allowed a low constant for the rivets, we may feel safe in leaving it as it is.



THE LOWER FIGURES ILLUSTRATE A TRIPLE RIVETED DOUBLE STRAP BUTT JOINT, AND A QUADRUPLE RIVETED DOUBLE STRAP BUTT JOINT, BOTH WITH UNEQUAL STRAPS.

We must now consider the joint from the point of view of possible failure, or as we say, analyse it. In a butt joint the rivets on one side of the centre line only are considered, as conditions on each side of the centre line are exactly the same. Taking the plate from the centre line it may crush in front of a rivet in the inner row and shear one rivet in double shear in the outer row. It may shear two rivets in double shear, or it may tear between the rivets of the inner row and shear one rivet in the outer row. It may tear between the rivets on the outer row, and this is usually the weakest point.

Suppose it crushes in front of one rivet and shears one rivet. We have

$$d \times t \times 90{,}000 + a \times 1.75 \times 42{,}000$$

$$\frac{3}{4} \times \frac{3}{8} \times 90{,}000 \times \frac{3}{4} \times \frac{3}{4} \times .7854 \times 7 / 4 \times 42{,}000 = 57{,}726$$

The unit section is $3.75 \times .375 \times 60{,}000 = 84\,000$ lbs. Therefore the percentage in this case is $\frac{57{,}726}{84{,}000} = 68.7$ per cent. which is lower than either percentage already obtained. If we look into this a moment we will see why. Comparing

this joint with the double riveted lap we see that although we have the advantage of the rivets being in double shear, for this particular case of crushing the plate and shearing one rivet, the greater pitch of the butt joint offsets this advantage. It is obvious that to bring this part of the joint up to a closer strength proportion, we must increase the rivet area. This will decrease the percentage of plate strength, but we shall have to make a compromise. By making the rivets 13-16 dia. instead of ¾ in. we shall get a closer relation.

First $\frac{3.75-.8125}{3.75} \times 100 = 78.3\%$ plate strength,

and $\frac{13x13x.7854x7x4x8x70}{16x16x2x15x3x100} = 90.3$ rivet strength.

Now to consider again crushing in front of one rivet and shearing one rivet in double shear.

13/16 x ⅜ x 90,000 + 13/16 x 13/16x.7854 x 1.75 x 42,000
= 27,414 + 38,106
= 65,520 lbs.

As the unit section is 84,000 lbs. we get

$$\frac{65,520}{84,000} \times 100 = 78\%$$

In the case of shearing two rivets we will have

13/16 x 13/16 x .7854 x 1.75 x 2x42,000 = 76,212 lbs., which gives a percentage of 90.

For tearing between one row and shearing one rivet we have

(p—d)t x 60,000 + a x 1.75 x 42,000
66,090 + 38,106

which gives over 100 per cent.

Tearing between the rivets of the outer row gives (p—d)t x 60,000 = 66,090, and this, of course, gives 78 per cent.

We have therefore a joint not very much higher in strength than a good lap joint, and considerably more expensive to manufacture. This is the reason that comparatively few of these joints are met with.

The Triple Riveted Butt Joint

Coming to the triple riveted butt strap joint, we have reached probably the most widely used joint in high class boiler manufacture. The efficiency of this joint is high, usually running about 86 per cent. It is not unusual to find the rivet strength in these joints considerably higher than the plate strength, and this is accounted for by the large number of rivets in double shear. The weakest part of the joint is the plate section at the outside row of rivets, and if this is high enough the rest will be pretty near right. The high efficiency is due to the large pitch in the outer row of rivets where each alternate rivet is omitted. In a joint of this type there are five rivets in a pitch, and of these four are in double shear, thus making 4 × 1.75 + 1 = 8 rivets practically, when considering rivet strength. The methods of considering the joint are exactly the same, except that the analysis is more complicated. After the dimensions are determined on, we must also check up and see that the diagonal pitch does not exceed the limit set by the Ontario regulations. We will take for purpose of example a double strap triple riveted butt joint, with unequal straps, and every alternate rivet omitted from the outer row, and an efficiency of say 86 per cent. The plate thickness is 7-16 inches.

The first step is to obtain the pitch for the outer row of rivets. With 7-16 inch thickness of plate, we can assume a 15-16 inch rivet. Then we have

$$\frac{p-d}{p} \times 100 = 86$$

$$p-d = .86p$$

$$d = .14p$$

And if $d = .9375$ then $p = \frac{.9375}{.14}$ which gives 6.69, or nearly 6¾. We can take this pitch as a basis to work on.

For rivet strength we shall have then

$$\frac{.69 \times 8 \times 4 \times 16 \times 70}{27 \times 7 \times 100} \times 100 = 130\%$$

Which is ample, being stronger than the solid section.

In how many ways can this joint fail? As in the last case, take from the edge of the plate and work outwards. The first case in which failure may occur is by crushing the plate in front of the rivets in the inner row, and shearing two rivets in double shear, and one rivet in single shear.

The unit section is

p t 60,000 = 6.75 x .4375 x 60,000 = 177,000
15/16 x 7/16 x 2x90,000 + .69x4.5x42,000
= 204,210

This is sufficiently high to allow it to be neglected.

In the next case the plate may tear between the rivets of the inner row, and shear two rivets in double shear, and one in single shear. This would be

(p—2d)t x 60,000 + ax1.75x2 + a x 42,000
= (6.75—1.875) x .4375 x 60,000 + .69 x 4.5 x 42,000
= 258,378

which is also above the unit strength. The joint may fail in the third instance by tearing at the second line of rivets and shearing one rivet in single shear. (p—2d) t x 60,000 + a x 42,000 = 156,948 and the percentage to unit strength is 88.6, which is higher than the plate strength at outer row.

If the joint fails through shearing all the rivets it will have to shear four rivets in double shear and one in single shear.

4a x 1.75 + a x 42,000 = 231,840

which is much higher than the unit strength. The last case to consider is tearing at the outer row, which is

(p—d)t x 60,000 = 15,258

and the percentage is 86.2, which may be considered the efficiency of the joint.

The minimum diagonal pitch is found for the inner and middle row from the formula, Diag. pitch $= \frac{3P+4d}{10}$

and for the outer and middle row $= \frac{D.P}{3}$

$= \frac{3}{10} P + d.$

The minimum distance between middle and outer rows is obtained from the formula

$$\sqrt{\left(\frac{11}{20} P + d\right)\left(\frac{1}{20} P + d\right)}$$

and for the inner and middle rows from

$$\sqrt{\frac{(11P + 8d)(P + 8d)}{20}}$$

We will not enter into the solution of these formulae immediately, but will use them when designing the actual joint for the boiler we are considering.

The Quadruple Riveted Joint

This is a further development of the butt joint, and is used where a very high joint efficiency is required. The rivet section in this joint is very large, there being eight rivets in double shear, and three in single shear, giving a total of 17 rivet areas in the joint. The outside strap covers only the two inside rows of rivets, and the third row of rivets leaves out every alternate rivet, and the outer row has twice the pitch of the third row. The efficiency of the joint will depend on the efficiency at the outer row, which will be as usual P—d. This pitch must never exceed 10 inches in any case. With a 90 per cent. joint the pitch of the outside row would be 9⅜ inches, that of the next row 4 3-16, and the inside row 2 3-32 inches. The joint may fail by crushing the plate in front of four rivets in double shear and three in single shear. It may tear between the rivets of the inside row, and shear four rivets in double, and three in single shear. It may tear across the second row of rivets and shear three rivets. It may tear at the third row and shear one rivet, or it may tear at the outer row. Shearing all rivets is hardly likely. The reason for fixing a minimum diagonal pitch is to preclude failure by tearing across a diagonal pitch line. The least value of the joint is the plate percentage at the outside row, and this, as we know, is 90 per cent.

We will take up in the next article the calculating of the boiler where we left it in order to consider riveted joints.

Will Rebuild.—The first sod of the new factory of the Imperial Steel & Wire Co. at Collingwood was formally turned by Deputy Reeve William Williams, in the presence of members of the municipal council, the chamber of commerce, and other business men. Lt.-Col. J. A. Currie, president of the company, said the new buildings would be much larger than those destroyed by fire in May, 1919, while the plant would be so expanded as to give an output of about 200 tons of wire products per day. Contracts for the building, Lt.-Col. Currie also said, have practically been awarded, local firms being the successful tenderers. Construction will be proceeded with immediately.

Cement Joints for Cast Iron Water Pipe

The Following From the Journal of the American Waterworks Association Will Be of Interest to Many Power Plant Engineers Who Have Work of This Kind

By GEORGE W. PRACY

Superintendent, Spring Valley Water Co., San Francisco, Calif.

TWO sections of 4-in. cast iron pipe, using cement instead of lead in making the joints, were laid in April, 1917, by the Spring Valley Water Co. This was in the nature of an experiment, none of the men ever having made a cement joint before. The line was thoroughly tested for leakage before being put into use and the results were so satisfactory that cement has been used in some 16,000 ft. of 4-in., 5,000 ft. of 6-in. and 16,000 ft. of 8-in. cast iron pipe laid since that time. No larger size mains were laid during or since the war period; had any such been laid, cement would have been used. Over one mile of these lines has been in use more than two years under 175 lb. pressure without requiring any repairs. An 18-in. line is about to be laid in a neighboring town in which cement will be used for making the joints.

The use of cement is pretty general along the Pacific Coast. Clark Shaw of Long Beach describes the use of cement joints in Long Beach, California, in an article printed in the April, 1917, Proceedings of the American Society of Civil Engineers. F. M. Randlett, of the Portland, Oregon, water works, in the 1916 report of the department of public utilities, recommends cement joints for all new work. P. D. Rice, formerly engineer for the San Jose Water Co. and now connected with the Spring Valley Water Co., used cement to a considerable extent in San Jose. The East Bay Water Co. of Oakland, California, the Los Angeles water department, as well as several smaller systems, also have used cement in some of their work.

Making the Joint

In making the cement joint, the spigot end is put into the bell just the same as for a lead joint. Two rings of jute or yarn are then put around the pipe and driven into the bell in the regular manner. The jute used must be free from oil or tar. In some joints the jute was put in dry and in some it was soaked in grout before being used. There was no apparent difference in the results.

When the jute is in place the cement is mixed. Neat cement of standard Portland cement brand is used. The mix is very dry, the proportions being about 13 to 14 lb. of cement to 1 pound of water. This leaves the mixture so dry that it will crumble readily when handled. At no time should the mixture be wet enough to become sticky. The mixing is done in a pan or bucket, enough cement for one joint being mixed at a time. At first the men guessed at the amounts, taking what cement and water they thought was right. Later, measures were used, calibrated to give the amount of cement and water necessary, including waste, for a 4, 6 and 8-in. joint.

When the cement is mixed ready for use, a canvas is placed under the joint to catch the waste. The operator takes a handful of cement and with an ordinary calking iron shoves the cement into the joint until the joint is full. He then takes a calking hammer and calks the joint until the cement is rammed in as hard as possible. The joint is then again filled and the operation repeated until the joint is completely filled with the rammed cement. At first a bead was put around outside the bell, but this was discontinued as being unnecessary. In handling the cement the men must wear gloves. After the joint is finished, it is covered with earth while the cement is hardening.

Amount of Cement Used

In putting the cement into the joints, considerable is lost, even though a canvas be placed to catch it. The amount used in making a joint depends entirely upon the carefulness of the operator. In some careful checks made it was found that from 5½ to 10 lb. of cement were used in making an 8-in. joint. On an average, however, a 4-in. joint will take 5 lb.; a 6-in., 7 lb.; and an 8-in., 9 lb. As cement out here costs less than one cent a pound, the cost for material is not very great and it does not pay to slow up the men by exacting the extreme of carefulness.

Cost of Cement Joints

Careful observation on the cost of lead joints made in laying over 45,000 ft. of pipe in 1915 and of cement joints made in laying the 37,000 ft. during the last three years, has resulted in the following comparative table of costs. The wage scales and material prices have been adjusted to meet present conditions.

	Size of Joints		
Lead Joints:	4-in.	6 in.	8-in.
Labor Calker at $5.50; leadman at $4.75	$0.527	$0.723	$0.850
Lead—at 9½ cents per pound	.831	1.165	1.495
Coal—at $14 per ton	.015	.025	.026
Total	$1.373	$1.913	$2.371
Cement Joints:			
Labor—$5.50 per 8-hour day	$0.30	$0.44	$0.58
Cement	.05	.07	.09
Total	$0.35	$0.51	$0.67
Saving per cement joint	$1.02	$1.50	$1.70
Saving per foot for 12-ft. lengths	.08½	.12½	.14

The cost of yarn, amounting to a few cents a joint, has not been included, as it is the same in both cases.

Initial Leakage

When water is first turned into the line with cement joints, every joint weeps badly and in some cases the water oozes out quite readily. In a few instances small pin-like streams have squirted out. In 24 hours this has practically all stopped and in two or three days the line is tighter than a line with lead joints.

On some jobs a meter was cut in on a by-pass around a closed gate so that the water to replace the leakage from the line was measured. The meter showed a leakage of 100 cu. ft. or more the first day, dropping to a few cubic feet on the second day and practically nothing thereafter.

Four sections of pipe, about 1,500 ft. long, tested for leakage at the joints after the water had been in the pipe for a week, gave the following results: In the first section the leakage was 1-3 gal. per linear foot of pipe joint per 24 hours. The second section leaked so slowly that the leakage could not be measured. The last two sections were practically tight, the line being pumped to pressure and left standing in one case for ½ hour and in the other case 2½ hours without any drop in the pressure.

Flexibility of Cement Joint

At San Jose a test section of 6-in. pipe was made, somewhat over 70 ft. long, using cement joints. This was first pumped to a pressure of 300 lb. without any leakage through the joints. The line was then put on supports so that it was elevated about 4 ft. off the ground. With a normal working pressure of 60 lb. on the line, all but the two end supports were knocked out, permitting the pipe to be self-supporting over a span of 70 ft. The pipe dropped 2 ft. in the centre without causing any leakage at the joints. The line was then again lowered until it lay flat on the ground, while under normal working pressure; still no leakage. It was then emptied and left empty, exposed to temperature varying from 40 deg. to 110 deg. F. for nearly one year, after which it was again filled and the joints were all found to be tight.

In the first block of pipe laid, containing about 40 joints, 3 joints had to be cut out and remade. Since that time only 2 joints have continued to leak after the water was turned on. Both these joints were repaired by cutting out only that portion of the joint that was leaking and calking in lead wool. The pressure had to be taken off the line while the work was being done. Cutting out the joints

on the 4-in. line took about 20 minutes. No joints in large pipe have been taken out.

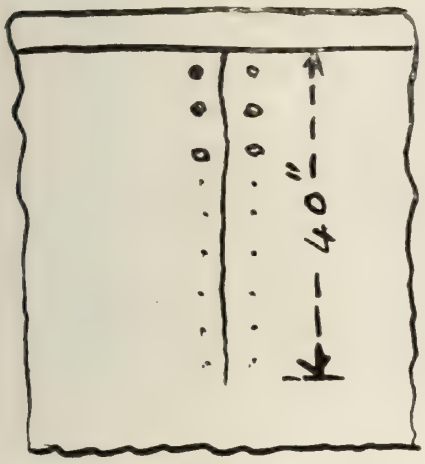
One indirect advantage of cement joins is that they act as insulating joints and reduce the amount of current carried by the line. This feature is of particular importance in the larger cities where electrolytic action has done considerable damage. The cement joint increases the resistance of the pipe as a conductor to such an extent that the current carried is negligible.

Taking all things into consideration, it is believed that the cement joint has come to stay. Improvements over the present methods of making the joint will undoubtedly be made, but even at the present cost they are cheaper than any other joint known, and from all the experience out here on the Pacific Coast they are entirely satisfactory.

*From the Journal of the American Water Works Association.

AN UNUSUAL WELD

A repair job of interest to all engineers was recently carried out by means of the electric arc welding process to the main engine cylinder of the steamer Chippewa.



SHOWING CRACK EXTENDING 40 in. DOWN FROM TOP OF CYLINDER, STUDDED READY FOR WELDING.

Our readers will be familiar with the Chippewa's old-fashioned beam engine or "walking beam," as it is sometimes called. Needless to say the engine only has one cylinder, so that when a vertical crack some 40 inches long developed in the cylinder wall during the busiest part of the season, something had to be done about it. The cylinder is 5 ft. 6 in. in diameter by 12 ft. long, and carries a working pressure of 60 lbs. per sq. in.

After consultation with the Lincoln Electric Co. as to the possibility of successfully welding the crack, it was decided to proceed with repairs as quickly as possible, by means of a method which has been very successful in repairing large iron castings subject to heavy working stresses.

Holes were drilled down each side of the crack, and steel studs were screwed in and cut off about 3-4 in. from the cast iron. By the time the last stud was in, the Lincoln Electric Co's. motor truck carrying the portable electric welding outfit was on the dock within 20 feet of the Chippewa's engine room. The cables were connected up and the welder went to work to weld those studs and the cast iron of the cylinder into a solid mass of metal. Twenty-four hours later the job was complete and shortly afterward the Chippewa steamed out into the lake for a trial trip.

The weld was found to be quite tight and appeared to be a perfect job. The Superintendent Engineer deemed it advisable, however, to make assurance doubly sure by re-inforcing the weld with two steel bands placed right around the cylinder.

Electric arc welding has been used extensively of late along the water-front in Toronto for boiler and hull repairs but this is one of the first local instances that has come to our notice of the use of the process for a major repair to a large and important iron casting.

FINISHED WELD RESEMBLING STEEL PLASTER ABOUT 1 IN. THICK, APPLIED TO OUTSIDE OF CYLINDER WALL FOR FULL LENGTH OF CRACK.

Note:—It was found that this method of welding had the effect of drawing the edges together and closing up the crack as the weld was made, from the bottom up.

WESTINGHOUSE STAFF PICNIC

Over 40,000 persons, employees of the Westinghouse Electric & Manufacturing Company, thir wives and families, attended the 34th annual outing and basket picnic at Kennywood Park, Pittsburgh, on August 14. This outing was featured by the many athletic events both for men and women of the company, a great many prizes being given to the winners. An event that created considerable interest was a baseball game between two girls' teams.

This picnic was one of the largest of many held in the Pittsburgh district by industrial plants and its success was due largely to the employees of the company who had complete charge of all arrangements.

Companies included in the picnic arrangements were: the Electric, Machine and Meter Works, East Pittsburgh; Trafford City Works, Trafford City; Linhart and Copper mill at Turtle Creek; Homewood service station and Pittsburgh Office, Pittsburgh and Braddock Foundry, Braddock, Pa.

VIEW FOR AEROPLANE PILOTS

A most ingenious invention is the "clear-view screen" which a British firm has produced for the benefit of navigators. Rain, spray, or snow renders it difficult or impossible to see through an ordinary port hole or other glass screen. The invention consists simply of a glass disc, which forms part of the screen and is rotated at so high a speed that any water or snow falling upon it is immediately spun off. The glass remains so clear that its rotation is extremely difficult to detect. This device has now been introduced on aeroplanes in order to assist the pilot when rain or snow encountered. The disc is driven either by a small windmill fixed on one of the struts, or by vanes fixed to the edges of the disc itself. When the aeroplane is travelling at 75 miles per hour the disc spins at 1,200 revolutions per minute. At anything over 800 revolutions the glass will keep clear in all weathers.

In connection with the forthcoming trans-continental air flight from Halifax to Vancouver, the Quebec Harbor Commissioners have been approached as to the using of Lampson's Cove as a seaplane harbor, which will serve as a permanent station for transcontinental flights, and will place Quebec on the all-red air route. Capt. Leroyer, of the Canadian Air Board, has stated that one of these flights will take place towards the end of this month. The object of these flights is not only of military value but it is to demonstrate the practicability of the airplane for commercial purposes.

The Superheater Company, Limited, will manufacture the type of fire-tube superheaters now in general use in locomotives of all Canadian railways, and also fire tube superheaters for marine installations, of which there are now over two thousand in daily service. In the case of the water tube boilers in marine service, the company designs and manufactures the superheater to suit each individual case. This likewise applies to stationary installations, either water-tube, fire-tube, or separately fired. The conditions are studied in each case with a view to supplying the most economical and effective installation. The company employs a form of return bend which is made by a forging process from the metal of the superheater pipes, making an exceptionally strong construction which is proof against high temperatures. This form of return bend has also been considerably sought after for the use in pipe coils for refrigerating purposes, condensers and other uses.

Can Anyone Prove It?

IN a newspaper report of a recent disaster on the Great Lakes, the statement is made that as the vessel was sinking, the boiler exploded. This is not an unusual statement, but we venture to say it has little but the reporter's imagination to back it up. Is there any good reason why a boiler should explode on a sinking ship? The thoughtless individual usually jumps to the hard-worked explanation of the sudden contraction and lets it go at that. What then does this sudden contraction perform? Does the shell contract so much that the pressure is increased beyond the resisting strength of the metal? Most assuredly not. The sudden contraction theory does not hold water. The fact is that the boilers do not explode when the ship is sinking. If they did, it would be of little use trying to salvage sunken steamers, as they would be damaged to such an extent that salvage would be impossible. Of all the steamers sunk by mine and torpedo during the war, were there any cases of boiler explosions unless the boiler shell was actually ruptured by a piece of shell, or other projectile? As a matter of fact, the boilers on steamers sunk and afterwards salvaged are usually found intact and fit for use again. This idea of the boilers on a sinking ship exploding is one that has been fostered by non-technical writers in the daily press, and accepted without question by men who should know better, and who would recognize the error of the statement if they gave the matter a little thought.

Looking for Ideas

FORBES' MAGAZINE, in a recent issue, refers to the success of Thomas Edison, and remarks "One invention was the result of 5,000 experiments. When he was working on his improved electric lighting he sent men into remote corners of the world in search of some fibre or other material which could provide the electric bulbs with the right kind of filament. Such is his spirit of enterprise that he reads more trade publications probably than any other business leader."

Leaders in manufacturing life in this country are coming to the point where they are depending more and more on the trade and business papers for help in their particular line of business.

Only a few weeks ago there was recorded in these columns the case of the master mechanic of one of the leading Canadian railroads. In going through one of the mechanical papers he found an idea that he was able to apply to his work in the shop, and by so doing saved the railroad company hundreds of thousands of dollars in time of repair, and also enabled the rolling stock to be put out much sooner in order that it might be earning revenue instead of eating its head off in the repair shop.

There is something worth thinking about here. If you put your ideas in print in a mechanical or technical paper you are sure of an audience of interested readers, and it is almost certain that some one is looking for the idea you have. The amount that may be paid for the material is only a small part of the service. It may not be very much, but it may be as much as the paper can afford. The big idea is that you can, through the medium of the technical pages in such a paper, pass along an idea that may be the means of giving great assistance to some mechanic who is having troubles of his own. The passing on of these ideas does not impoverish the person having them, neither is he enriched by withholding them.

Trade Follows the Flag

THE saying which is used as a caption for this article is not always true. In some cases, and perhaps the majority, the flag follows trade, and it is in this manner that the British Empire has been developed. The originators of the Canadian Government merchant marine, however, saw that the possession of a fleet of modern commerce carriers, which could go to all parts of the world, could become a great drawing power for Canadian trade, and that in this case trade would follow the flag. The Canadian Government fleet, conceived in the first instance as a measure to tide the shipbuilding yards over a doubtful period, has expanded into a ship-owning concern that will have no less than sixty-six first class modern cargo carriers under its flag. This flag is the flag of the Dominion of Canada, and it does not require a very great imagination to see what an advertisement for Canada this fleet can be. Sailing from Canadian Atlantic and Pacific ports, these Canadian built and Canadian manned steamers will carry holds full of goods manufactured in Canada to every port on the shores of the seven seas. This fleet would justify its existence were it as a great advertising scheme only, but it has already justified itself as a commercial success. The Canadian Government Merchant Marine is a fleet in being, of which every Canadian can be justly proud.

Progress in New Equipment

RECENT DEVELOPMENT IN SMALL VACUUM PUMPS

By F. A. McLean

As the successful outcome of a long series of experiments and tests the Ingersoll-Rand Company recently placed on the market a new line of small vertical vacuum pumps which will be known as their "Imperial Fourteens."

These little machines are built in six sizes at present, and are said to be far superior to any machine of their rated capacity heretofore obtainable, in fact, it is claimed that they will deliver from two to a hundred times as much air as any other pump of the same piston displacement and will require less power per cubic foot of air handled, regardless of the degree of vacuum maintained.

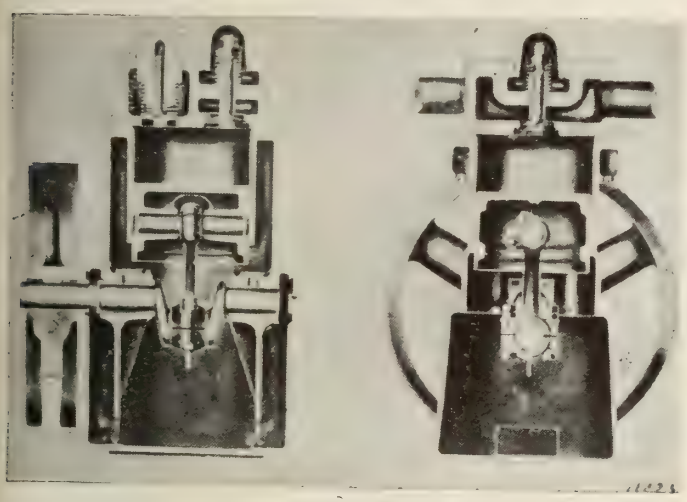

FIG. 1—CROSS SECTIONAL VIEW OF 2, 3, 4, AND 5-INCH STROKE VACUUM PUMP, SHOWING NOVEL METHOD OF COOLING.

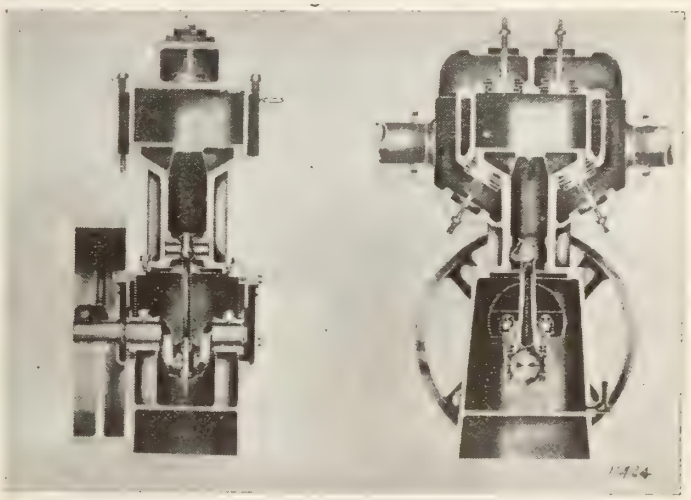

FIG. 2—CROSS SECTIONAL VIEW OF 10 x 5 AND 12 x 6 INCH PUMPS, SHOWING CONSTRUCTION OF "T" PISTONS AND ARRANGEMENTS OF PLATE VALVES.

In such points as the design of the frame, drop forged crank shaft, and connecting rod, renewable die cast bearings, accurately balanced flywheel, automatic splash lubrication system and freedom from oil on their exteriors, these pumps resemble the company's "Imperial Fourteen" compressors which were brought out a year or two ago.

The four smallest pumps are of the single acting type and have air cooled cylinders measuring respectively 4, 5, 6, and 8 inches diameter by 2, 3, 4, and 5 inches stroke. By a novel method of cooling, the need for water jackets or fragile and unsightly vanes or ribs is done away with. Cooling is accomplished by the "breathing" of the crank case, which takes place through an annular space around the cylinder; thus on each stroke of the piston, air is alternately drawn into and forced out of this "air jacket" through two special openings, the location of which may be noted by referring to the right hand sectional drawing in figure one.

The two largest machines, 10 x 5 and 12 x 6 (illustrated in figure two), although of the double acting type, are singularly free from the usual complication of piston rod, stuffing boxes, crosshead, and crosshead guides usually found in machines of this class. Due to their larger capacity, the cylinders are provided with integral water jackets. The pistons on these machines—as will be seen by reference to figure two—are similar to a letter "T" in cross section and are provided with an opening or chamber sufficiently large to accommodate the piston pin, and small end of the connecting rod.

Pistons in all six machines are manufactured to very close limits and are fitted with a 3 piece and one snap ring, assuring maximum tightness without sacrificing simplicity or strength.

On the 2, 3, and 4 inch machines, inlet and discharge valves of the mushroom poppet type, made from chrome vanadium steel, so proportioned that breakage is almost impossible, are used. The valve springs are carefully adjusted to permit easy opening and quick closing of the valves, and a cap screwed into the opening over the inlet valve prevents any chance of leakage at this point. The discharge valve guide is screwed into the cylinder head, thus making the discharge chamber tight; a feature that is desirable at all times, and especially so where a pump is required to handle gases at discharge pressures of one to four or five pounds.

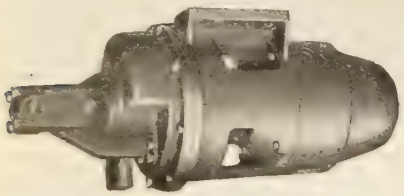
Plate valves, consisting of a flat disc of special valve steel held from any lateral movement by the tension of a light spring steel guide plate to which it is permanently attached, are employed on the 5 and 6 inch stroke machines. Coil springs held in a stop plate bear on the valve disc and force it against its seat with definite and predetermined force. Valves of this type have been found to be absolutely tight throughout their life.

The tightness of the valves and piston rings used, the efficiency of the design and the excellence of the workmanship, in combination permit the maintenance of very high vacua. The three largest machines have a pulling capacity of 29 to 29.25 inches of vacuum, while the smaller machines equipped with poppet valves will pull 28.6 to 29 inches, depending on the size.

These pumps are adapted for use in connection with vacuum filters, pans and kettles, vacuum melting and digesting apparatus, milking machines, evaporating and distilling equipment, steam condensers, air dryers, impregnating and insulating machinery, industrial and experimental research laboratories, glass manufacture, the canning and bottling of foodstuffs, etc.

SMALL TURBO GENERATOR SETS

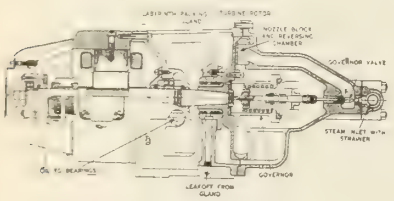
Although developed especially for supplying energy for locomotive headlights, the turbine-generator units just placed upon the market by the Westinghouse Electric & Manufacturing Company



may be used for lighting service in small isolated steam plants such as pumping stations, small steam shovels, oil well derricks and in other applications where a small amount of lighting is required. The construction is especially advantageous for portable application, as it is designed for severe outdoor service.

This unit is small, light and compact, requiring no foundations. It can be set up on a floor, heavy board or in any horizontal place and held in position with four small bolts, studs or lag screws.

While totally enclosed all parts are readily accessible by removing the end cover on the generator and the turbine end casing on the steam end. There



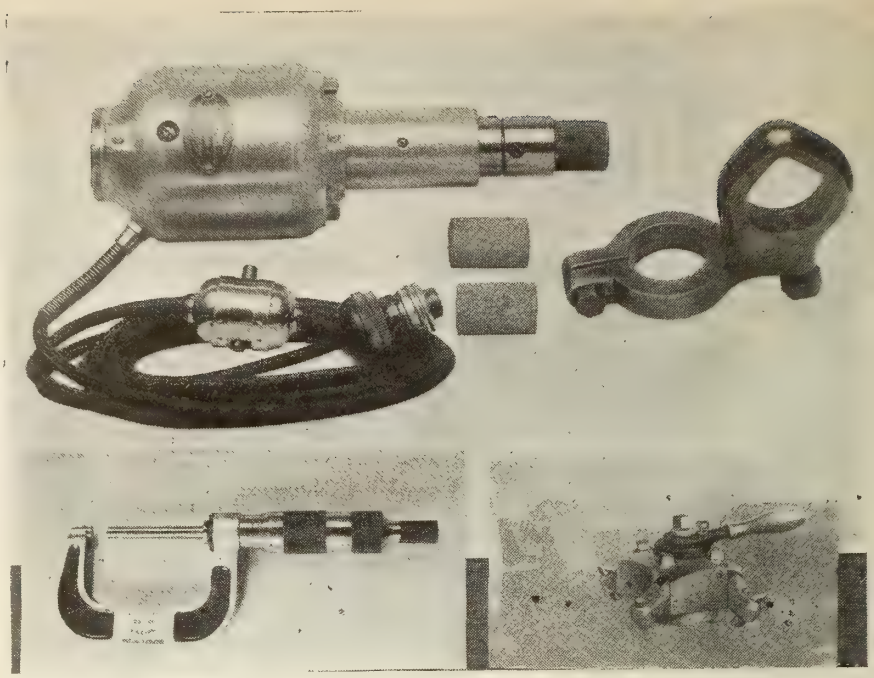
are only five moving parts—the shaft carrying the generator armature and the turbine rotor, two governor weights, governor spindle and governor steam valve stem—thus making for simplicity of operation.

As there are no levers to wear and stick and no packing to adjust and renew, no adjustments are necessary after the unit leaves the factory.

The unit is self-contained, each part being built for each other. The single shaft carrying the generator armature and turbine rotor with governor is supported by two standard self-aligning ball bearings at each end of the armature—the turbine rotor with governor being overhung.

The generator end consists of one casting containing one bearing and the field poles with windings. To this is bolted the middle section, which carries the second bearing and holds, by a web, half of the turbine rotor housing.

This middle section supports the whole unit. The steam space, governor valve and steam strainer are contained in the third or turbine casting. This construction eliminates all chance of temperature distortion, insures no leakage of steam to the generator, and gives a rugged perfectly balanced unit.



TOP VIEW SHOWS GRINDER, LOWER LEFT HAND VIEW THE MICROMETER, AND REMAINING VIEW THE TOOL POST.

BLUSH MULTIPLE MICROMETER

A. T. Blush Tool Co., 1145 West 11th St., Erie, Pa., have placed on the market the micrometer as illustrated. The purpose of the instrument shown is to eliminate the necessity of using two instruments in taking measurements ranging from 0-in. to 2-in. This is accomplished by the use of two threads of different pitches, namely, a 20 pitch for the measuring screw and a 40 pitch for the thimble carrier. Although the mechanism embodies two screws, the accuracy of the instrument depends only and entirely upon the 20 pitch thread as the 40 pitch thread only functions in keeping the thimble in proper alignment with the graduation on the hub.

The difference in the pitch of these threads makes it possible to obtain a 2 inch movement of the spindle with only a 1 inch movement of the thimble. The adjustment for wear on the anvil and the spindle is taken care of without moving either the anvil or the measuring nut which makes a very desirable feature as it is impossible to throw the anvil and the spindle out of parallel when making adjustments.

Due to the fact that the spindle is actuated with a 20 pitch thread this makes a very fast acting instrument as the thimble travels half as fast as the spindle. Another feature is the graduation, which is said to be much easier to read than the old style of graduation.

It is their intention to make these instruments in larger sizes having a range of 2 inches on each size, also a special instrument for very close work ranging from 0 inch to 1 1-2 and 1 1-2 to 3 inches.

STERILISATION OF SOLUTIONS

Many ideas have been tried out relative to the sterilisation of cutting solutions, but the most successful one for the average industry, according to "Safety Engineering," is to have a set of drains running from the machine to a large pit consisting of two large tanks. The solution is run into one tank, which collects a great deal of the sediment, and then over to the other tank to be used again. Each week, and sometimes twice a week, the solution is taken out and the pit cleansed thoroughly. The solution is then returned to the pit, if it is not broken down, and is heated up to 148 deg. by steam pipes running through the pits, and maintained at that temperature for a half-hour. This process has been in successful operation at the plant of the Ford Motor Company. Examination with the microscope of the solution at the Ford plant showed from 10,000,000 to 15,000,000 bacteria per cubic centimetre in the infected solution, whereas but 400,000 to 600,000 bacteria per cubic centimetre appeared in the sterilised solution.

PLANER IMPROVEMENTS

The Cincinnati Planer Co. have incorporated a number of changes in the design of their planers which add to the serviceability of the machine. The top arch is now being made of the box pattern, which gives increased strength and bearing surface on the housings. The cross-rail is likewise of the box type and it is claimed that increased rigidity is a feature when the tools are cutting. An automatic stop has been added to the machine so that the clutch for elevating the cross-rail may be released at any desired point in the vertical range. Improvement has also been made in the holding device for the tool post harp.

The Operators' Point of View

ILLUSTRATING REPAIR ON TUBE SHEET.

BUILDING UP A LIGAMENT IN A TUBE SHEET

By R. McLAREN

Recently a tube in a return tubular boiler sprang a leak of such a nature that the metal was eroded from part of the ligament, as indicated by the sketch. Putting in a tube would only have meant that the tube would have been cut through in a short time at the point of erosion unless the depression were first built up. We had both the torch and the arc processes available in the plant, and on account of its greater convenience, it being portable, the torch was advocated by some for doing the job.

However, the high temperature to which the metal over a considerable area must be raised before deposition of the filler can be effected makes the torch objectionable for such a job, the contraction stresses resulting being such as to possibly strain the ligament. The deposition of the filler by the arc process being instantaneous, no overheating can result.

PORTABLE LIGHT STAND

By JOHN THORN

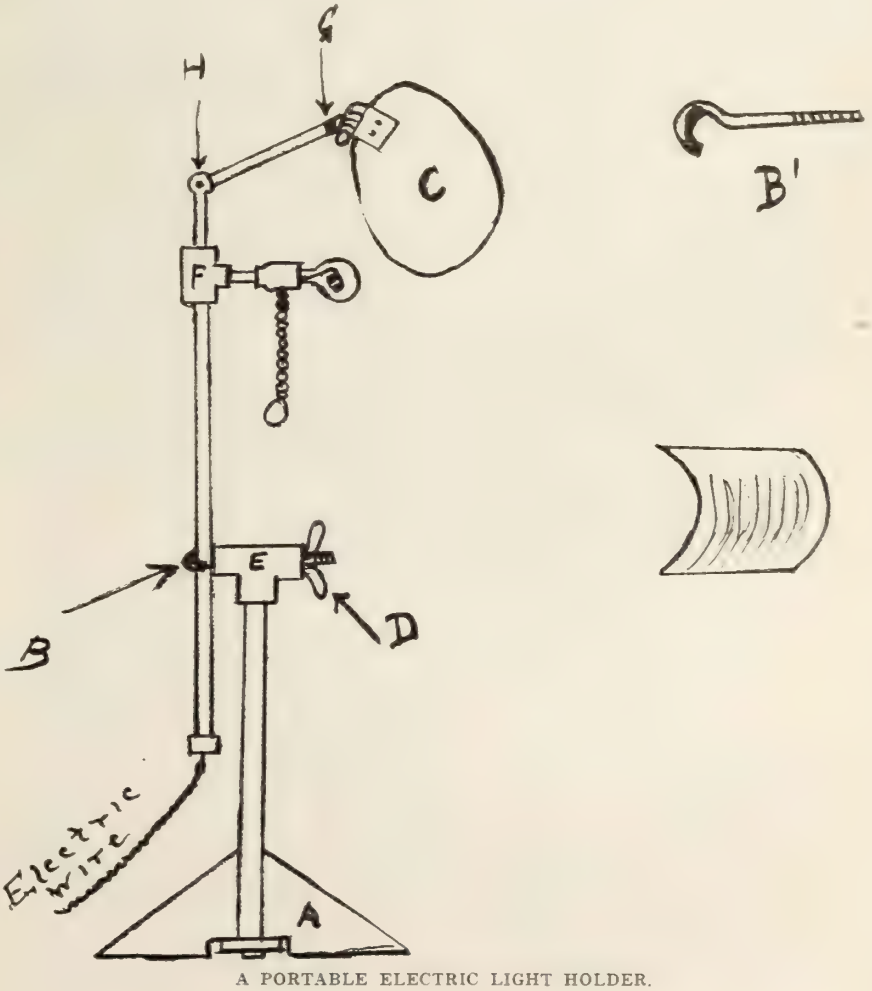
The sketch shows a useful, easily made, portable electric light lamp with adjustable height arrangement and an adjustable reflector; a threaded socket is attached to one side of the reflector at C, and the hinge at G and joint at H are held fairly stiff by using a small threaded bolt, by these means the reflector can be moved in any direction, so that the rays of light will be directed where needed. The reflector can be bent into the shape shown at Fig. 2 if desired.

The piece B is shown in B¹, on the end of it is a wing nut D.

The base A is made from scrap lead, the standard is a piece of ¾ inch iron pipe with a lock-nut on the bottom and a ¼x¼x¾ tee on the end at E.

The pipe F is a ⅜x⅜x⅛ inch tee.

When the whole lamp is put together and nicely bronzed it has a fine appearance.



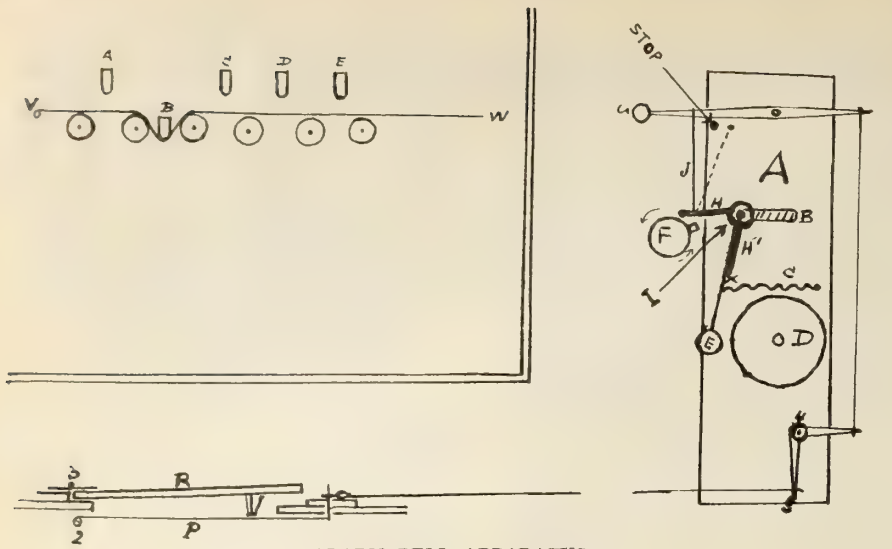
A PORTABLE ELECTRIC LIGHT HOLDER.

ALARM BELL SIGNALS

By J. E. McCORMACK

Even slight freezing damages dry cells to some extent and they can be ruined by frost. During the past winter when using dry cells in cold places I was obliged to be careful about them freezing and return them to a house at night. The enclosed sketch shows how alarm bell signals may be worked without cells or a battery providing their use is where machinery is in operation. I had not yet "happened on this" and was not using it when carrying the cells about.

A is a piece of board in an upright position and into which a slot to hold a coil spring B is cut, D is a bell or gong and C is a coil spring which pulls the hammer E to hit the bell or gong. F is a shaft belonging to some part of the machinery in operation, which



ALARM BELL APPARATUS.

of course must be guarded, but the guard must permit access of the said device to the shaft. H H¹ is a bell crank which swings on axis I. The arm of the hammer E also swings on axis I, but independently of H H¹ except that H¹ can pull the arm and the hammer E away from gong D. J is cord from H to the weighted lever arm above; its purpose is to hold H away from shaft F. If H drops to the shaft F then the key shown, or some projection provided, raises H by passing under it until upon reaching the highest point of travel it passes from under H, allowing H to drop again. H in rising pulled E away from the gong by means of H¹ and when H dropped then spring C drew E against gong D. If the hammer arm is rigid a rubber buffer or a flat spring must be placed at X to force the hammer a little away from the gong again instantly else the device will make merely a series of hits instead of producing a ringing sound. If the hammer arm is itself springy enough a pin at X will suffice. The exact location must be found by experiment. If the device is set up at a shaft end then a pin in the end of the shaft and enough from center to act as a crank will serve to raise H; but to prevent H falling too far again an elastic cord (indicated by a broken line in the sketch) will be required to support it, but the cord must not be too tight. The remark above as per guards applies here also. Another method would be to put on to the shaft two split safety collars a little way apart and with a triangular or a half round piece between them and its ends recessed into each a little bit, its flat side concaved slightly to fit the shaft snugly enough that if the shaft were to revolve backward H could not run under the piece and get caught or broken. The idea of the elastic cord with the pin-in-end-of-shaft method and of the coiled spring B with the key or the two-collars-and-the-piece-between methods is to allow the shaft to revolve backward without doing damage to the device and the same applies to the idea of having H H¹ and the hammer arm pivoted independently on I for then H¹ cannot break the hammer arm by forcing it too hard against X or D.

From the other end of the lever arm above them to which J is attached a cord passes down to one arm of a bell crank below, and from the other arm of this piano wire, or some other light wire, passes to the trip device shown to the left in the sketch. P, hinged at 2, has its other end bent at right angles and passing up through the floor or a board and through a ring attached to the end of the fine wire used. R, hinged at 3, and having its other end held up by a spring, has a projection on its under side and when pressed down by a weight coming on to it from above the projection comes against P, forcing it down and thus releasing the ring on the end of the wire and allowing the weight G to lower and slacken cord I, thus allowing H to engage the projection on the shaft F, the final result being the ringing of the bell or gong; one stroke being made per each rev. of F. A pin must be inserted some place in board A where it will prevent G dropping much further than is necessary.

Before trying it I thought the bell from an alarm clock would do for D but I found something larger was required. One of the old fashioned dinner bells is more like suitable.

As compared with dry cell circuits the above has the disadvantage of requiring to have the ring replaced over the end of P each time, but for cold weather it has the advantage of immunity to damage from frost. Then, too, bells are not left ringing and exhausting the battery for a time at noon or night because a switch has been forgotten.

As for the use of R, a belt falling onto it (crosswise) indicates that the belt is off. A conveyor chain falling onto it (lengthwise) indicated that the chain is broken or is off the wheel. A tank float may be made to press it, a door or gate to push it, or if it is wide enough pedestrians crossing it will step on it. One can set it for any one of several signal requirements. In the event of wishing to connect up a number of the P-R devices to one gong the insert in the sketch illustrates an idea that can be utilized. Let A B C D and E in the insert represent bell crank arms, corresponding, in service to the bell crank arm 4-5 below D. The circles represent small pulleys or sheaves G and changed over to the other end of its lever, and the cord V W is so connected that when tightened the effect is to slacken cord J and allow D to ring. It is obvious that any one of the arms A to E, in the insert, will, if allowed to drop, tighten the cord V W to cause the ringing of D. The set may be placed as best suits the surroundings and the direction in which the trips or P-R devices lie.

CLEARANCE IN GASOLINE ENGINE

Question

We would appreciate very much if you will publish in your next issue of Power House the proper size of combustion chamber for a marine gasoline engine. The engine is water cooled by a continuous stream of cool water being pumped through the engine while running. As an example, say we take an engine with a 5 in. bore and 4½ inch stroke, what is the proper size of combustion chamber when piston is up?

Answer

The amount of clearance or combustion space in a gasoline or any internal combustion engine, is governed by the required compression pressure. The compression pressure in an engine of the type mentioned is usually from 60 to 80 lbs., according to the ideas of the manufacturer. The ratio of compression is found from the formula

$$(p\ v)^{1.35} = (p.\ v.)^{1.35}$$

absolute pressures, of course, being used.

This formula gives the final volume into which the suction air is compressed and is the adiabatic ratio of the compression for stroke and clearance. If we subtract this from 1, we get the ratio for obtaining the clearance. This is done by dividing the stroke by the ratio, and subtracting the stroke. thus

$$\frac{\text{stroke}}{\text{ratio}} - \text{stroke} = \text{linear clearance}$$

This gives us

$$\left\{\frac{14.7}{84.7}\right\}^{1.35}$$

This must be worked by logarithms, and we get

log 14.7=1.167317
log 84.7=1.927883

T.239434

This must be multiplied by 1.35, the product being T.03323, the number corresponding to which is .108. Subtracting this from 1 we get .892, which is the ratio we want. Then

$$\frac{\text{stroke}}{\text{ratio}} - \text{stroke} = \frac{4.5}{.892} - 4.5 = .547 \text{ ins.}$$

The volumetric clearance will be

$$25 \times .7854 \times 4.5 = \text{stroke vol.}$$

$$\frac{\text{stroke volume}}{\text{ratio}} - \text{stroke volume}$$

which gives

$$\frac{88.375}{.892} - 88.375 = 10.675 \text{ cub. ins.}$$

The above shows the method of obtaining clearance. The amount of compression depends on the ideas of the designer.

Trade Gossip

Have Contract.—A contract for the mechanical equipment of the Hudson's Bay Company's store at Victoria, B.C., has been awarded to Greene and Lister, plumbing and heating contractors, Winnipeg.

A Busy Shop.—Favorable reports are received regarding operations by the Ontario Steel Products, Limited. The plant at Gananoque, where shovels are made, is running at capacity, and business at the other factories is also reported to be very good.

Toronto.—Mr. F. S. Wood, formerly Agent for the Canadian National Railways at Pittsburgh, is being transferred to Toronto to look after the interests of the Canadian Government Merchant Marine. Mr. Wood has been located at Pittsburgh for the past five years.

Build Machine Shop.—The Gunnel Company of Canada, 2410 West Dundas Street, Toronto, received a permit from the city architect for the erection of a three-storey brick and reinforced concrete machine shop, which, when completed, will cost in the neighborhood of $100,000.

Vancouver.—The Canadian Pacific Railway coast-service will be augmented by a new steamer which will replace the "Princess Sophia" which was lost last year in the Alaskan straits. The contract has been let to the Wallace Shipyards of Vancouver, and the vessel will be 326 feet long with a speed of 17 knots. She will cost about $1,500,000.

Make Steel in West.—Rolling mills and blast furnaces for the manufacture of steel, will, it is expected, be established in this province as soon as the necessary market for the product of such an undertaking has been assured, according to a statement made by Major Martyn, Industrial Commissioner for the province, who, with James H. McVity and Nichol Thompson, of the Advisory Council of the British Columbia Department of Industries, has left for Chicago and San Francisco in connection with the matter.

Want Yards Open.—Business Manager Herbert Wright, of the Toronto Union of Shipbuilders, is in Ottawa conferring with the Minister of Marine and Fisheries, urging that they proceed with the construction of the two ships on the ways of the Dominion Shipbuilding Company. These were started before the company was forced into liquidation. The third vessel, that was under way for a New Orleans firm, is being finished by the owners. Mr. Wright will urge upon the Government the fact that if the work does not go on many men will be out of work this winter.

Change in Welland.—The plant of the Dillon Crucible Alloys, Limited, Welland, has been purchased by the Canadian Atlas Crucible Steel Co., Limited, and Canadian interests will be strongly represented in the company as well as on the board of directors. Atlas products, which include "L-XX" brand of high speed steel and other Atlas brands, carbon and special alloy tool steels, will now be made in Canada. The general sales office of the company will be located at 133 Eastern Ave., Toronto, Ont., with a warehouse in conjunction, and branch warehouses and sales offices at 326 Craig St. W., Montreal, also at Winnipeg, Man.

Toronto.—The Canada Steamship Lines will build a new steamer for their Lewiston service, which will be in commission for next season. She will be the largest passenger boat in the fleet, and will be thoroughly modern in every respect. She will be propelled by geared turbines, and will have a speed of about 22 knots. She will have four decks, and a restaurant, dancing floor, moving picture theatre, and a children's playground are spoken of. Pressed steel fittings will be used entirely in the interior, reducing the fire risk to a minimum Passenger accommodation will be provided for 4,000.

B. C. POWER DEVELOPMENT

The development of the Bridge River power site near Lillooet, Vancouver, is in its initial stages, surveying and preliminary work now being carried on. The plans, which will involve the expenditure of 30,000,000 dollars, call for a tunnel a mile and a half long under Mission Mountain, discharging into Seaton Lake, six miles from Lillooet. The fall will be 1,400ft., and it is estimated that 400,000 horse-power will be developed.

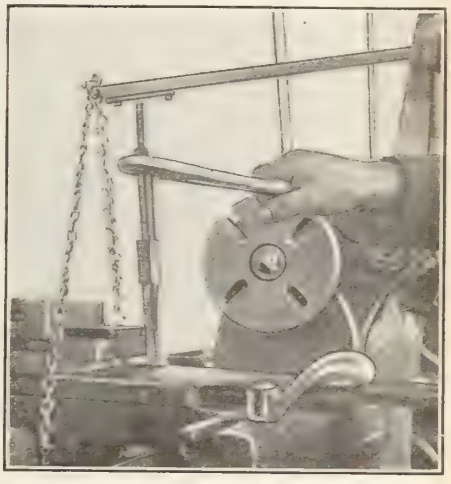
ELECTRIC HAULAGE ON BRITISH CANALS

Plans have been drawn up for the application of electric haulage to an important section of the canal which connects Birmingham with the Severn. The speed of the barges will be raised to double the limit with horse haulage, but no damage to the banks from the wash is anticipated. Current will be supplied from an overhead trolley to the electric haulage gear. Investigations are also being made into the use of electric battery haulage for canal barges. The whole question of the future of British canals is now being considered by a special committee formed by the ministry of Transport.

ACKLAND SCREW DRIVER

The screw driver as depicted is the product of the Ackland Specialty Co., Springfield, Mass. It is said that this driver will remove any rusted or stuck screw which could not be budged by an ordinary driver.

The principle involved is an old established law of mechanics. A few pounds of pressure at the end of the upper bar and on the rachet handle results in a much greater pressure at the slot of the screw. This feature of course eliminates the danger of the driver slipping and ruining the screw slot.



HOW THE SCREWDRIVER IS USED.

Automatic and machine manufacturers are said to be especially interested. The blades are made from special heat-treated and tempered steel. The post is attached to the blade by a case hardened socket and sliding on the post is a rachet which permits using the driver in narrow and restricted places. The cross bar is secured to the post by a ball joint permitting movement in all directions.

The chain is attached on the end of the cross bar and looped around some projecting lug of the machine. A glance at the photo illustrates clearly the method of using.

Trying the Coal.—E. H. Oliver, chief engineer of the Alberta Government power plant, has been sent to Winnipeg to conduct a series of tests with Alberta coal for the purpose of demonstrating to consumers in that province that coal from Alberta will stand the shipping and the climate conditions and will burn well.

Canal Work Handicapped.—Work on the Welland Ship Canal is held up on account of shortage of coal, shortage of Hydro power, and shortage of labor. While there is hope of overcoming the latter difficulty, there is not much hope for overcoming the first two. When work stopped last year there were 2,500 men working on it. There was little chance of the same number being employed this year.

COPPER-ALUMINUM-IRON BRONZE AS AN ACID-RESISTING ALLOY

By O. L. Kowalke

Copper-aluminum-iron bronze is known to possess many valuable qualities. In tensile strength it ranks with mild steel. It can be forged while hot, and also rolled into sheets; it can be machined to a nice finish, and sound castings can be made of it, free from shrinkage-holes and blowholes. These among other qualities render the alloy suitable for bearings and gear. But very little has hitherto been known concerning its acid-resisting properties. With a view to acquire knowledge in that direction, a systematic series of tests have been made at the University of Wisconsin laboratories. The results of these tests, which were made with various acids and alkalies, are set out for detailed comparison in three tables. Only two of the bronzes experimented with are reported on; they are distinguished as A and B. Their average compositions and properties were:

	Bronze A	Bronze B
Copper	87.0 %	85.6 %
Aluminium	9.8 %	10.81%
Iron alloy	3.14%	3.57%
Ultimate unit stress	74,800 lb. sq in.	66,600 lb. sq. in.
Reduction in area	19.0 %	13.0 %
Elongation in 2 in.	21.0 %	11.5 %
Specific gravity	7.71%	7.58%

The specimens for the corrosion tests were approximately 1 in. by 0.07 in., and were finished smooth, with square edges. Most of the tests were made at room-temperatures of 72 deg. F. and 85 deg. F., but a few were made at 194 deg. F.

Bronze A was found to be resistant to several acids, particularly to sulphuric, lactic, phosphoric, tartaric, and acetic acids. Nitric acid attacked the metal readily, the concentrated acid acting violently. Hydrochloric acid and ammonia solution both attacked the metal too readily for commercial purposes. Caustic soda had but little effect. In the case of bronze B, a strikingly higher resistance to sulphuric acid is shown. Also ammonia did not corrode it so readily as bronze A. Nitric acid attacked bronze B also too readily; and hydrochloric acid attacked it more readily than bronze A. It is interesting to note that the corrosion, in 35 per cent. sulphuric acid, of a forged specimen of bronze A is only about half that of the rolled-sheet and cast forms.

ELECTRICALLY DRIVEN PUMPS.

At a meeting of the Institution of Water Engineers, held at Birmingham, Mr. C. F. Bekenn, A.M.Inst.C.E., contributed a paper on "The Application of Turbine-pumps to Water Supply." In the course of the paper the author remarked that while turbine-pumps could be driven by any type of prime mover, he placed the electric motor in the first place as regarded efficiency and convenience. The installation costs, including foundations, were low, and the space occupied was small. The pump and motor required very little attention, as the bearings were automatically lubricated with oil-rings. Low installation costs permitted the sets to be conveniently

THE E.S.MANNY Co

27 COTE ST MONTREAL, CAN.

To Buyers' Directory Page 50

distributed. They were easily started up, and could also be operated from a distance or automatically stopped and started, either by varying levels in the reservoir or by varying pressures between pre-determined limits. The alternating-current motor was preferable to the direct-current machine owing to the absence of a commutator, and most of the installations at work were driven by A.C. motors. If a heavy current rush on starting was permissible, it was advisable to install squirrel-cage motors, as the turbine-pump, owing to its low-starting torque, could easily be started up by this type of motor. One point that had to be noted was that the slip between synchronous and asynchronous speeds could not be exactly determined, and might vary as much as 2 to 4%. The B.H.P. required to drive the turbine-pump varied as the cube of the speed, so that should the slip be less by, say, 2% than the makers' original estimate, the B.H.P. would be considerably increased, with a proportionate increase of water. For squirrel-cage motors, auto-transformer starters of the oil-immersed type should be installed, with no-volt and overload release on the three circuits, these operating in the stator circuit. The starter consisted of a transformer with tappings on the windings, of varying percentages of the line voltage. The tappings should be selected as best suitable for the starting torque, and as that was not more than 50% of full load torque, a low percentage, say, 25 or 30%, was sufficient. The automatic features were arranged in the "running" position only, because in the "starting" position they would at once break the circuit owing to the rush of current, which was generally two or three times the ordinary running current. This type of starter required only three terminals on the motor and six on the starter—namely, three for the motor and three for the line. In cases where low starting currents were necessary, slip-ring motors should be installed, as those would start up with 50 per cent. of full load torque using normal running current. With reference to motor terminals, trifurcating boxes were recommended as providing an extremely neat finish and effectively enclosing all the live parts. In large pumping-stations, where the current had to be carried some distance and the motor-power was at least 150B.H.P., the motors could be wound for 6,000 volts, and so dispense with transformers. For motors of less than 150B.H.P. a lower voltage was necessary on account of the difficulties of insulation in the coil windings.

Proceeding to discuss the relative costs of steam and electric pumps, the author gave several examples as showing that economy was on the side of the latter. Thus, the City of Hereford had three electrically driven pumps working off a three-phase, 50-cycle circuit, two sets delivering 60,000 gals. per hour, and the other set deliver n~ 20 000 gals. per hour, against a total lift of 120 ft. in each case. The costs, as recently determined, showed that with electricity at 0.75d. per unit, the cost of electric pumping was 0.5d., as compared with 0.426d. per 100,000 gals., the cost of steam pumping. Those figures included men's wages, lubricating oil, waste, etc. The Newbury District Water Company, early in the year 1912, made careful tests of its compound condensing steam pumps, and of its electric pumps. The latter were driven by direct-current motors, one set having a capacity of 30,000 gals. per hour against 185 ft. lift, one set 20,000 gals. per hour against 150 ft. lift, and a further set 3,000 gals. per hour against 164 ft. The 1912 costs worked out at 1.18d. per 100,000 ft.-gals. for steam, as against 0.957d. for electrically driven pumps, but for 1920 the figures are 2.61d. and 1.576d. respectively. The Chester Waterworks Co. had installed a Diesel engine and dynamo supplying power to drive turbine pumps built by Sulzer and the Rees Roturbo Company, at two separate stations connected by cable. The costs, including all transmission losses and "shut-downs" due to interruption in working consequent on erection of additional plant, came to 0.657d. per 1,000 gals. 100 ft.

You Try This

When you desire any information on matters pertaining to the trade it will be gladly furnished free upon application through the columns of this paper. If you enclose stamped, addressed envelope we will also reply direct to you. Don't hesitate to ask us. We will do our best.

BOILER ROOM FOREMAN WANTED — CAPable of assuming entire charge of operation and maintenance of large steam plant. Must be a man of proven ability and understand the principles of combustion, able to organize his department in such a manner as to obtain efficient and economical operation. Good salary and permanent position to the right man. Reply giving details of previous experience to Box 14920, Power House.

WANTED
One Water-Tube BOILER

New or second-hand—Babcock & Wilcox—400 Horse Power, good for 200 lbs. Must be in first-class condition. Send price and particulars to E. R. Gray, City Engineer, Hamilton, Ont.

Saves Labor—Saves Steam Saves Products Being Spoiled

These are some of the advantages of installing Sarco Temperature Regulators to automatically regulate your temperature conditions.

The action of the Sarco is so positive and dependable that it is being used extensively for some of the most delicate manufacturing processes. Also widely used for controlling the temperature of rooms. Is suitable for operating steam, gas or water valves.

SARCO
Temperature Regulator

is a complete power plant in itself. Requires no air compressors, electricity, water supply or anything else to make it work. Can be installed in 60 minutes without any outlay for materials.

Has no rubber or leather diaphragms or other perishable parts. Costs less than others to start with. Costs nothing for upkeep.

To prove the Sarco's superiority without cost to you, we'll ship one on 30 days' free trial.

When you write, ask for Booklet.

FAIRBANKS-MORSE

FAIRBANKS-MORSE QUALITY F M 100%

Mastering the Waters of the World

Mastering of the waters of the world has been and is an important factor in the advancement of civilization. The Canadian Fairbanks-Morse Co. Limited, claims its share in this advancement.

No matter where you live, or what your business, you are constantly dependent on pumps for the water you drink, for the protection of your home from fire, or the production of the things you use, wear, and eat. And quite likely it is a Fairbanks-Morse pump, for Fairbanks-Morse pumps have long been recognized as standards—dependable pumps, constantly giving maximum service under the most exacting conditions.

The Canadian Fairbanks-Morse engineers know the pumping problems of Canada and, with all the resources and reputation of this national institution behind them, have developed pumps that meet every requirement and meet it with a product that is worthy of being branded "Fairbanks-Morse 100% quality."

Make this mark your guarantee of satisfaction and our catalogue your buying guide.

Republic

CO_2 RECORDER

Is it not a fact that you, Mr. Engineer, have been looking for a CO_2 Recorder that will operate accurately and continuously?

You have not found this because the REPUBLIC has not, until now, been placed on the market.

Can you imagine a CO_2 Recorder with

NO SMALL TUBING, the smallest ¼" internal diameter;

NO GLASS tubing or otherwise;

ONLY TWO MOVING ELEMENTS—one a single unit with no moving parts and the other consisting of a float with Pen Arm on a staff and Pen Retainer?

The whole apparatus actuated by the flow of water and controlled by a syphon system which operates regardless of any change of flow in the water supply, insuring continuous flow of gases from the furnace.

Each charge for analysis is taken from the passing gases. The gas is forced 2 in. into the absorbent solution and must flow 8 in. through the solution before it can rise to the surface, thereby insuring complete absorption of the Carbon Dioxide.

No complication of mixture of fluids, such as Caustic Potash, Oil, Mercury, etc.

The instrument is complete in one case, making it convenient for adjustment, yet the chart may be changed by opening the small door and not disturbing the instrument proper, exposing it to dust, etc.

This instrument is not an experiment, having been in operation without stoppage or attention for three and a half years.

DEPARTMENT OF LABOUR
Ontario Government

Minister: Hon W. R. Rollo — **Deputy Minister: W. A. Riddell, Ph.D.**

NOTICE TO STATIONARY AND HOISTING ENGINEERS AND STEAM PLANT OWNERS

Everyone operating a **Stationary** steam plant of 50 B.H.P. or over, and everyone operating a **Hoisting** steam plant working at a pressure of 20 pounds or over, irrespective of horsepower and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a certificate from the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

After January 1, 1920, all stationary steam plants in the Province of Ontario must be registered with the Board of Stationary and Hoisting Engineers. Application forms will be forwarded upon request.

All applications should be mailed to the Chairman of the Board. W. C. McGhie, Department of Labour, 15 Queen's Park, Toronto.

NOTICE TO MANUFACTURERS, DEALERS AND USERS OF STEAM BOILERS

All steam boilers built in, or entering, the Province of Ontario, and boilers exchanged or repaired, are subject to Government Inspection as prescribed in the Steam Boilers' Act, 3 George V., ch. 61.

Before any work of repair or alteration is commenced on any boiler, notice must be sent to the Department stating the nature and extent of the repairs or alterations proposed to be made. If the Chief Inspector should consider such repairs or alterations of an extensive character, the boiler must be inspected in accordance with the Regulations by an Inspector authorized under the Act.

All communications should be addressed to the Steam Boiler Branch, Department of Labour, 15 Queen's Park, Toronto. D. M. Medcalf, Chief Inspector of Steam Boilers.

Weir Pumps
For Feed and Other Duties

Weir Feed Pump
Weir Service Pump
Weir Twin Compound Feed Pump
Weir Tandem Compound Feed Pump
Weir Hydraulic Pressure Pump
Weir Turbine-Driven Rotary Feed Pumps

In addition to our standard pumps, we have a large variety of designs for special duties. For high duty installations for water or oil, we can supply special patterns, simple, compound or triple, for pumping against pressures up to 1,000 pounds per square inch.

WEIR SERVICE!

With Weir Power Plant Auxiliaries we furnish something which is difficult of definition, something which for want of a better expression we call **Service.**

To offer to our customers the whole resources of our organization—Research, Designing, Manufacturing and Operating—this service is one of the foundation stones of our ideas of business.

After thirty years of concentration on specific lines, it is natural that we should have accumulated a vast amount of specialized knowledge which is of vital assistance in the solving of our customers' power problems. Our experience, our data, and our results we place at their disposal. We may have just the information required. If this is the case the value of Weir Service is at once apparent.

Such is the aim of our organization—to serve our clients efficiently, satisfactorily and to the full extent of our ability.

COPPUS TURBO BLOWERS EFFECT STEADY SAVINGS

In the modern plant of the New York Ice Company, New York City, this 22" COPPUS Turbo Blower has been saving time, money and labor ever since installation in April, 1917. It has **made possible** the use of cheap fuel, and **made sure** the maintenance of constant steam pressure. So satisfactory has been the service of this COPPUS Blower that two more blowers have since been purchased for other plants of the New York Ice Company.

COPPUS Turbo Blowers are cutting down fuel costs and keeping up steam pressures in cold storage and artificial ice plants all over the country. Automatically regulated, self-oiling, quiet-running—COPPUS Turbo Blowers are by far the most efficient means of securing mechanical draft.

Let our engineers tell you just what COPPUS Blowers can save you in your boiler room. Write for Blower Catalog.

"COPPUS" Equipment can "Save You Money"

PLIBRICO

Better Than Fire Brick

Jointless Furnace Lining for Industrial Boilers

It can be used for front door arches, side walls, bridge walls and rear arches and wherever fire brick can be used. It is also unexcelled for baffle construction and repairs. Made for hard service and fuel economy.

Easy to Install

Shipped in steel containers only. Warehouse stock carried in principal cities for immediate delivery.

Write for book on furnace building.

1000 Percent More Work

That's what lubricant does for hack saw blades.

Look at the chart above. Three identical blades cutting the same piece of stock. Two of them were run without lubricant—and in each case failed in less than five cuts. The third made over 50 cuts and was still cutting when the test was stopped,—because it was flooded with lubricant.

—That's just one of the charts in "Hack Saws and Their Use". There are more of them in this new Starrett Book, showing the effects of different cutting speeds and weights. There's also the Starrett Hack Saw Chart.

If you use hack saws, you need "Hack Saws and Their Use". Write for a free copy and for Catalog No. 21 "(D)"

'Bishop's Adamant' Gauge Glasses

Will resist all Steam Pressure and Variations of Temperature.

REFLEX GAUGE GLASSES

Annealed and Hardened for
LOCOMOTIVES, STEAM WAGONS, MARINE AND STATIONARY BOILERS.

Adamite Gauge Glass Rings. Glass Tubes and Rod

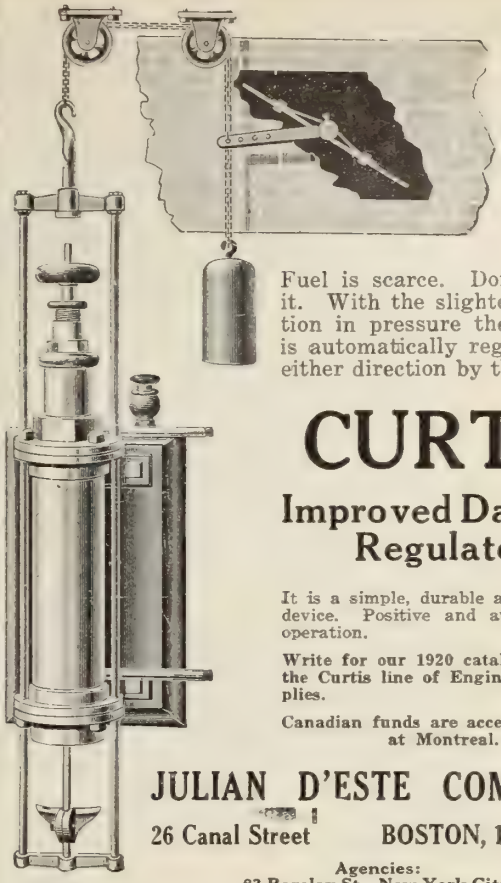
S. & C. BISHOP & CO., St. Helens, Lancashire.

LADD
WATER TUBE BOILER

The Ladd Water Tube Boilers are designed throughout to withstand heavy firing. Built in any size and for any of the many methods of firing.

Our catalogue will interest you.

THE GEORGE T. LADD COMPANY
First National Bank Building
PITTSBURGH - - PENN., U.S.A.



Save Fuel

Fuel is scarce. Don't waste it. With the slightest variation in pressure the damper is automatically regulated in either direction by the

CURTIS
Improved Damper Regulator

It is a simple, durable and effective device. Positive and automatic in operation.

Write for our 1920 catalog showing the Curtis line of Engineering Supplies.

Canadian funds are accepted at par at Montreal.

JULIAN D'ESTE COMPANY

174 North Market Street, Chicago, Ill.

HOMESTEAD
Quarter-Turn Valves

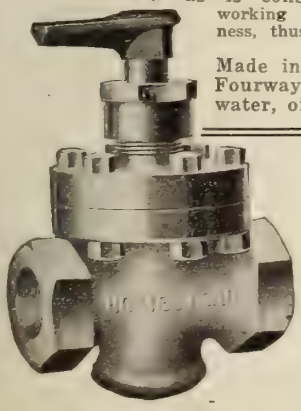
Simplicity is Their Dominant Feature

It is the simplicity of Homestead Quarter-Turn Valves, in operation and in construction which makes them so effective and dependable.

Instead of the six to ten turns of wheel necessary to ordinary globe or gate valves, a quarter-turn only is required to change a Homestead from absolute tightness to a straight, unobstructed flow, or vice versa.

The Homestead is as simple of design as is consistent with efficiency. All working parts are of exceptional thickness, thus ensuring long, reliable service.

Made in Straightway, Threeway and Fourway patterns for air, steam, water, oil and acids.



Homestead Valve Mfg. Company
PITTSBURGH, Pa.
Works: Homestead, Pa.

FOR REMOVING SCALE

from Babcock, Stirling and other Water-tube Boilers and Evaporators, also for Lancashire Boiler Scaling and Rust Removing—there is no tool made to equal my

'SKATOSKALO'
Pneumatic Tube-Scaling Tool.

Simple, strong, speedy, reliable---these words describe its efficiency
